MAGNETICAL AND METEOROLOGICAL OBSERVATIONS.

00133489

NOTICE.

The results of the Observations of the year 1846, have not yet been received from Mr. Orlebar, by whom they are being prepared for the Press; but at the special request of that Gentleman I have not delayed the publication of the present volume on that account; they will be published when received in the forthcoming volume for 1847.

The labour of passing the volume through the Press has been diligently and carefully performed, under my directions, by Serjeant Dunn, and Keru Luximon.

CHS. WM. MONTRIOU,
Commander, I. N.
In Charge of Observatory.

OBSERVATORY; COLABA.

INTRODUCTION.

SITUATION OF THE OBSERVATORY.

THE island of Colaba, on which the Observatories are built, is a narrow island, with a S. & N. direction, bending a little to the east, nearly two miles and a half in length. It is continued towards the south in a long reef, called the Prongs, which is exposed for more than a mile at low water. The base of the Lighthouse is its highest point, which, according to levellings made by the Engineer class of the Elphinstone Institution under Professor Pole, is 47·49 ft. above the level of the floor of the tidehouse, which is about the height of highest high water. The Observatory compound is a little to the north and east of the Lighthouse. The base floor of the large Magnetic Observatory by the same measurements, which are presumed to be accurate to half an inch, is 19·48 above the tidehouse floor. The formation is greenstone trap, which decomposes into a rusty soil. There are a few mangoe and borah (zizyphus lotus) trees within the compound, but no other than the latter, excepting shrubs, within some distance of the Magnetic Observatory. The shore slopes gradually away on the western side of the island towards coral reefs and the open sea, and on the east slopes for some distance until it suddenly sinks into the deep water which forms the entrance to Bombay Harbour. A public road traverses the island from the Fort of Bombay to the Lighthouse, which bounds the Observatory compound on the west, and the sea bounds it on the east. Its Magnetometers can therefore be very little affected by accidental disturbing causes as the presence of iron in its neighbourhood; and as a Meteorological Observatory, it is perfectly free from the influence of hills, radiation from houses, and other circumstances which might vitiate the best conducted observations. Its results may be considered as accurately those of a small island closely connected with the land.

The longitude appears to be $4^h\ 51^m\ 19^s$ and the latitude 18° 53′ 30″ from the observations hitherto taken at the Observatory.

HISTORY OF THE OBSERVATORY.

The Instruments now in use at Bombay were originally intended for Aden. But the Officers, who had engaged to superintend them, dying, the Royal Society considered

that Bombay would be an eligible station, and at the request of Col. Sykes, I attempted a duty which I felt to be quite consistent with my duties in the Elphinstone Institution, and had great pleasure in taking a share in an undertaking, in which the people and Governments of Europe have been more unanimous than in any other during the range of modern history, and to accomplish which the Court of Directors had made so liberal an expenditure. The instruments were accordingly put under my charge on the 15th March, 1841. Unfortunately both the Royal Society and the Makers had forgotten to send me any directions and instructions whatever, and I was not a little dismayed at finding myself, not only without guidance as to the nature of the building, but also as to the parts and objects of many of the instruments which were of course quite new to me. That instructions were given, is evident from a letter from Professor Lloyd, which was found in the Secretary's Office; but I have not been able to discover how they were lost. Capt. Boileau, at Simla, was the nearest Superintendent, and he obligingly sent me down a copy of the Royal Society's instructions, which did not however reach me until after the rains had set in. Previously, however, Mr. Caldecott, the Superintendent of the Travancore Observatory, passed through Bombay, on his way from England, and to his kind assistance I was indebted for sufficient information to commence the work without any further delay.

The distance between the meridian lines passing through the Declination Magnetometer and the Transit Instrument of the Astronomical Observatory, is 117 feet to the east. But the centre of the Declination Magnetometer is 225 feet to the north of the Transit Instrument.* This position of the building makes it possible to prevent any disturbances from iron, it being thus considerably within the Observatory enclosure.

The soil round about is tolerably even and is of greenstone and decomposed rock of red earth, which will therefore act pretty equally all around. The floor is raised about a foot from the soil, and is of chunam. The walls 20 inches thick, are of a shelly limestone which now forms in some parts of the Bombay beach. Their height is 14 feet to the eaves. The roof is of tiles with slopes to the north and to the south. The tiles are no doubt partly magnetic, but there was no remedy, and it was thought that the great height of the roof would cause the effect of the little iron within them to be insensible. The roof is also ceiled. It is lighted by nine windows, each of which is glazed and also venetianed. Through the centre of the roof and dividing the wall is a transit slit, which in the roof is closed by shutters, and in the walls by glass and venetians as the windows.

The three principal instruments of the Observatory, viz. the Declination, Horizontal Force, and Vertical Force Magnetometers are of the same construction as those de-

* Measured by Keru 16th July, 1845.

scribed in the Royal Society's Committee Report of 1840. They are all raised on pillars of masonry, in which the stone is gypsum. The pillars are surmounted with teak wood $2\frac{1}{4}$ inches thick, and upon this the instruments stand by their own weight.

The Declination Magnetometer is placed under the transit slit about 2 feet from the northern interior wall of the building. Its reading telescope is placed on a block of teak, which is fixed on the teak cover of the pedestal. Thus to whatever changes the Magnetometer might be subject, to the same its reading telescope would be liable.

The Horizontal Magnetometer is on a pillar with exactly the same arrangements.

The Vertical Force Magnetometer is on a rectangular pillar, whose upper surface is 3 feet by $1\frac{1}{2}$ foot.

The positions of these instruments will be best understood by referring to the ground plan; where D is the Declination, H is the Horizontal, and V the Vertical Force Magnetometers.

In order to determine the absolute declination, a transit instrument by Dolland was placed in the meridian line of D. in order to determine the absolute declination, as it was known that the declination was but a small angle.

As I had no time to work out Professor Lloyd's Problem of the best position of the instruments, or to obtain the solution from other quarters, I considered that it would be adviseable to make one large room in which the magnets would be sufficiently distant from one another to be free from mutual disturbance. The size of such a room would make it large enough for an Office, and it also could receive the Meteorological Instruments. For I saw no objection to exposing the Magnetometers to the free air in a climate of so uniform a temperature as ours. The Thermometers and Hygrometers were therefore placed on a stand M. which is in the currents of air through the windows E. and W. and through W6. and W2. The object of the other windows was to let in as much air through the venetians at its natural temperature as possible. The Barometer is fixed on the wall at B.

C is a stand for Chronometers. T. and T. are tables where registers are kept and all office work done.

At d, a portable Declination Magnetometer has been placed latterly, and at t, is a Theodolite by which its readings are made.

Through the exertions of Capt. Goodfellow, then Superintending Engineer, I was enabled to have this building erected before the rains. My numerous avocations of course obliged me to give less time than I could have wished to the work, and numerous difficulties, particularly in setting up the Bifilar, occurred through my previous

ignorance of the instruments, and from my destitution of assistance; so that I was obliged to work out the mathematical theories of most of the parts of the Vertical and Horizontal Force Magnetometers. This necessarily added greatly to the delay, so that it was not until the first week in September that the Magnetometers were permanently fixed. In all this, I was greatly aided by the zeal and intelligence of my pupil Keru Luximon.

The establishment then sanctioned consisted of three non-Commissioned Officers from the Sappers and Miners, who arrived on the 11th October, 1841. They were not however of much use at first, as during that unhealthy part of the year, they suffered much from sickness. The zeal however and industry, with which they labored, enabled me to carry out a much more extensive series of observations than those contemplated by the Royal Society, until the 1st May 1842, when sickness compelled me to leave India and the magnetic researches. Two of the assistants, Serjeant Dunn and Corporal Saul, continued to exert themselves to the utmost until the day of my departure. The third behaved in a dishonest manner, which compelled me to apply for his return to his corps, as I could no longer place that confidence in his truthfulness, without which nothing could be relied on. I expressed consequently my fears in a commuication to Government that his observations might not be trustworthy. This, however, I am happy to say, I subsequently found was not the case. On projecting the curves of the horizontal force, I could see distinctly that no deceit could have been used.

The observations were carried on hourly; for I could do this easily by dividing the differential observations between the three assistants, and making the absolute determinations myself with Keru Luximon. Serjeant Dunn also assisted at the absolute determinations. Sickness and the removal of one assistant broke a little the continuity of the series, although both myself and Keru assisted in the differential observations. But the series were so complete that all the Magnetic and a large proportion of the Meteorologic changes were determined. Those interruptions which did occur will, I believe, prove of no importance.

The term days were observed from the 1st November, inclusive.

On resuming the superintendency, in April 1845, I found the Establishment to consist of

Serjeant Dunn, from Sappers and Miners.
Keru Luximon.
Ananta Ballal.
Gunesh Narayan.
Dinsha Dorabjee.

The Government had, in addition to those of 1841, supplied a set of small Magnetic instruments.

1. Unifilar Magnetometer.
2. Bifilar Magnetometer.
3. Induction Magnetometer.
4. Portable Unifilar Magnetometer.

These instruments are constructed according to the descriptions in Lieut. Riddell's Magnetical Instructions, only the Induction has but one iron cylinder.

5. Declination Magnetometer.

I have given the above names, as they are those used in the descriptions referred to above; but when hereafter mentioned they will be spoken of as

1. Small Declination Magnetometer, No. I.
2. Small Horizontal Force Magnetometer.
3. Induction Magnetometer.
4. Small Declination Magnetometer, No. II.
5. Small Declination Magnetometer, No. III.

For the reception of these instruments a small Observatory has been erected at the north east angle of the large Observatory. The ground plan of this is given in plate III. The floor is of mud, the foundations of shell sandstone, the wall of bamboo plastered over, and the roof of cajans. There are no windows in it. The bamboos are cut away round the top so as to allow a cool current of air under the ceiling; and it is further kept at an equable temparature by two copper ventilators, one in the north and the other in the east wall. I am indebted to the Superintending Engineer, Capt. Turner, for his assistance in the plan and for facilitating its early erection.

DIURNAL CHANGES OF DECLINATION.

These have been observed hourly by two instruments, the Large Declinometer and the Small Declinometer No. I.

THE LARGE DECLINOMETER is of exactly the same construction as that described in the Report of the Committee of the Royal Society for 1840. It will therefore be needless to describe it, except in such particulars as are not there noticed.

The dimensions of the bar Magnet, which has been in use, are in parts of a foot and of a grain.

length = 1·25
breadth = 0·0715
thickness = 0·0208
weight = 0·6203

The Magnet has been suspended by the same number of threads as I found it on the 1st April.

The value of each scale division was thus determined: The Magnet with its Collimator was placed in a line with the telescope of a small altitude and azimuth circle, whose circle reads off to 5′ and that is easily read off by micrometers to seconds. And the middle wire of the telescope was made to coincide successively with the several divisions of the scale and the corresponding azimuth readings made.

Reading of		Differences.		Value of one Division of Scale.
Scale.	Circle.	Scale.	Circle.	
	° ′ ″		′ ″	′ ″
24	198·34·14			
30·0	197·53·11	6	41·03	6·50·6
35·0	197·18·50	5	34·21	6·52·2
35·0	197·17·04			6·49·6
24·0	198·32·09	11	75·05	
24·0	196·31·06	20	2°16′42″	6·50·1
4·40	198·47·48			

Mean value of one division 6′·50″·5 or 410″·5 = 6′·341

The Zero point of the declination bar was determined by reversals of the Magnet between $8^h\,44^m$ and $9^h\,21^m$ 18th April, five readings being taken at each reversal, and the following table contains the results:

18th April	Mean of 5 readings by Reading Telescope. Direct Position.	Rever. Position.	Half the sum of Dir. and Rever.
$20^h\,47^m$	21·1893	—	25·2404
$20^h\,50^m$	—	29·2916	25·2723
$20^h\,53^m$	21·2531	—	25.2840
$21^h\,05^m$	—	29·3150	25·1629
$21^h\,11^m$	21·0108	—	25·1029
$21^h\,13^m$	—	29·1950	25·0537
$21^h\,18^m$	20·9125	—	25·0704
$21^h\,21^m$	—	29·2283	25.1891
	21·1449		
		Means	25·1719

The most uncertain combination is the 4th, for then there was the longest interval between the observations, but this is nearest to the mean, therefore we may conclude that the Zero point is as near as possible to 25·17.

The readings are made by the central wire of the Transit, and therefore every hourly observation is an absolute determination.

In order to destroy internal radiation as much as possible, the interior of the box and the glass covers were gilded, the whole was carefully covered with white cloth, and the edges of the box upon the marble slab as well as the glass vessel over the torsion circle, were well filled up with bees' wax. This was completed by Serjeant Dunn before the 20th of April.

The readings are of course in scale divisions. But by the assistance of a table, the observer immediately reduces them to absolute declination. This table has been thus constructed:

First, a table was calculated, shewing the distance of the axis of the magnet from the central wire of the transit in minutes of arc for every ·01 of a division, which is smaller than can be read by our best observer. The zero of the axis is at 25·1719 of the scale. Consequently the declination is nothing at 25·172; and since when the readings increase, the north end of the magnet moves eastwardly, greater readings than this indicate eastward declination, and less readings westward declination. The vertical argument is the scale reading to tenths of a division. The horizontal arguments are hundreths of a scale reading.

Secondly, another table was prepared by correcting each of these for torsion. This correction was found nothing when the reading circle gave 21·099, and therefore the transit read 25·995. The correction is therefore applied with a + sign to easterly readings greater than 26 and to all westerly readings, but with a minus sign to all easterly readings less than 26.

Both these tables were constructed by Sergeant Dunn and Keru Luximon.

From the 13th of June, when they were completed, a copy of the last table was hung over the registry table, and when the observer entered his observation he took down the corresponding arc reading from the table and entered it into an abstract form, and these are the results which are entered as our observations from page 10 of the Magnetical Observations. In order to anticipate any future doubts it has been considered expedient however to publish the tables in order that if necessary they may be reduced back again.

No correction for azimuth has been applied.

March 2^d 19^h. The observation was taken 10^m after the proper time, the light being extinguished.

April 24^d 15^h. The eye glass of transit was out of position.

May 13^d 18^h. The lamps being out of order, the reading was delayed 10^m.

15^d 16^h. The observation 10^m after the time.

June 18^d 15^h. All three large Magnetometers making large vibrations.

Nov. 2^d 4^h-13^h. During these ten hours, the induction bar was used in experiments then conducted within the building; and in consequence 0·318 scale reading = 2·274 must be subtracted from each of the readings at this time.

Small Declinometer, No. I.

This instrument was at the beginning of the year on a wooden pillar 4 feet high in the N. W. angle of the Small Observatory. It is of exactly the same construction as the unifilar Magnetometer, described in page 60 of Lieut. Riddle's Magnetical Instructions, with the exception that it has no bell glass over it.

The Magnetometer box was attached to the pillar with white lead. The scale was read with the Reading Telescope, which had been used for the Large Declination Magnetometer previous to the exclusive use of the transit instrument. This also was fixed on a wooden pillar 5·5 feet distant from that of the Magnetometer. A solid cylindrical magnet marked A.54. is suspended by two threads of silk. Its dimensions are

length = 2·990 inches
diameter = 0·30

1845 August 22^d The following measurements were made:

distance of the scale from the mirror = 66·05 inches
length of one division of the scale = 0·20
length of the whole scale = 40·00

Let then a be the number of minutes in the angle subtended by the scale between the centre of the scale and the division read, and let a' be the angle.

Let β be the number of minutes, β' the angle measured in the same way on the supposition that the scale is not a straight line but an arc of the circle to which it is in fact a tangent. Then β is always greater than a. Let $\kappa = \beta' - a'$. Let γ' be the number of minutes subtended by one division of the scale on the latter supposition. Then

$$\gamma' = \frac{3437{\cdot}75}{66{\cdot}05}\,\frac{2{\cdot}0}{2} = \frac{3437{\cdot}75}{660{\cdot}5} = 5'{\cdot}20$$

$\therefore \beta' = n \times 5'{\cdot}20$ n being the number of divisions from the centre of the scale.

$$\text{Now } \tan 2a' = \frac{q}{r} = \frac{n \times 0{\cdot}2}{66{\cdot}05} = \frac{2n}{660{\cdot}5}$$

$$\therefore a' = \frac{1}{2}\tan^{-1}\frac{2n}{660{\cdot}5}$$

$$\therefore a' = \frac{3437'{\cdot}75}{2}\left\{\frac{2n}{660{\cdot}5} - \frac{1}{3}\left(\frac{2n}{660{\cdot}5}\right)^3 + \&c.\right\}$$

$$\therefore \kappa = \beta' - a' = \frac{3437'{\cdot}75}{2}\left\{\frac{1}{3}\left(\frac{2n}{660{\cdot}5}\right)^3 - \&c.\right\} = n\ 5'{\cdot}20\left\{\frac{1}{3}\left(\frac{2n}{660{\cdot}5}\right)^2 - \frac{1}{5}\left(\frac{2n}{660{\cdot}5}\right)^4 + \&c.\right\}$$

or $\kappa = n \times 1{\cdot}'73\left(\frac{2n}{660{\cdot}5}\right)^2$ nearly.

August 22. Torsion having been nearly destroyed by suspending the plummet, the Magnet was suspended and the co-efficient of torsion determined.

Reading of Torsion circle	30°	120°	300°	30°
,, of Scale.	94·95	95·11	94·81	94·95

Hence $\frac{H}{F} = 0{\cdot}00014$

and co-efficient of torsion $= 1{\cdot}00014$

hence the correction for torsion will be only ·01 of a scale reading, supposing the detorsion plane to be at one end of the scale, and the readings to be taken at the other; this correction therefore is entirely omitted in our Observations.

The line perpendicular to the scale was determined by measuring the distance from the centre of the Magnet to the scale, and thus determining the shortest line. The reading of the scale, where this perpendicular meets it, was determined to be 95. It is thought that this is accurate to half a division.

On the 24th, 25th, 26th, and 28th August, the readings of the Small and Large Declinometers were compared as shewn in Tables IV. and V. On projecting the curves however, a discrepancy was observed with regard to the changes of the Large Declinometer, which led to the examination of the lamp used during the night with the large declination. The result proved that the lamp was magnetic, although apparently entirely of copper. The comparison therefore was resumed on the 2d September *with* a satisfactory result, and it was found that there existed between the two Magnetometers a constant difference $= 4'$.

A table of absolute declination was then formed from the scale readings with this constant difference. It was hung up over the register table of the Small Observatory, and the determinations registered as for the Large Declinometer. These are the quantities registered under the head Small Declination Magnetometer until May 29^d.

Feb. 25^d. 15^h—16^h. Observations $7\frac{1}{2}^m$ before the right time.

May 3^d. 23^h. The telescope was shaken.

It has been observed (page (3) Results of Declination Observations 1845) that both the wooden pillars upon which the instrument, and that upon which the scale was fixed, had begun to crack soon after their erection; and eventually from this cause so much disturbance had been caused in the position both of the instrument and of the scale, that the results would supply no conclusions for annual changes, although the form of the day-night curve was unaffected. On this account, in the month of June, the instruments in the Small Observatory were taken down, and pillars of Porebunder lime-

stone were substituted for the wooden pillars. The instruments were then again replaced and the adjustments made by Serjeant Dunn, and Keru Luximon.

June 18^{d}. The instruments embedded in the stone with white lead; and not touched again until they were firmly fixed.

June 21^{d}. 23^{h}. The Magnet was removed, and the brass weight attached; the torsion destroyed, and the Magnet replaced.

22^{d} 0^{h}. 5^{m}. The mirror adjusted; and the following measurements made:

distance of the scale from the mirror = 65·76 inches
length of one division of the scale = 0·20 inch

and hence $a' = 5'23 = 5'\text{-}13''.8$

With this value of a' was formed a table shewing the value of the scale in minutes of arc; and in order that this might shew the true Declination, the readings of the Large and Small Declinometers were compared for two and seventy hours on the 24th, 25th, 26th and 28th June. The result was, that when the telescope read 30·0, then the true Declination is 13′42; and that 2′27 is to be subtracted from every value of a' to give the true readings. Tables therefore having been calculated and hung up as before, the observations recommenced July 21^{d}.

Nov. 4^{d}. 2^{h}. The induction bar, being brought near, affected the instrument.

DIURNAL CHANGES OF HORIZONTAL FORCE,

have been observed with two instruments. One is the Large Horizontal Force Magnetometer in the Large Observatory, the other is the Bifilar or Small Horizontal Force in the Small Observatory.

The Large Horizontal Force,

by Grubb, of Dublin, is of the same construction as described in the Report of the Royal Society, and as the adjustments were the same as those there directed, I shall refer to them for those which we made, giving only the results; and I shall use the notation there employed.

During the month of January the adjustments and corrections remained the same as last year, and had been determined as follows:

1. *Scale Reading of Collimator.*

The Collimator, fixed near the altitude and azimuth circle with its scale vertical,

and the readings of the verticle circle taken as the middle wire of the Telescope, was brought to successive lines of the scale.

Scale. Readings.	Vertical Circle.		Correct Reading.	Differences.	
	South Microscope.	North Microscope.		of reading	for 1·00
	° ′ ″	° ′ ″	° ′ ″	° ′ ″	′ ″
17·00	87·57·07	87·56·35	87·56·51		
5.50	85·47·04	85·46·39	85·46·46	2·10·05	10·50·04
11·00*	86·50·29	86·49·46	86·50·03	1·03·17	10·32·03
17·00	87·56·29	87·56·04	87·56·27		
5·00	85·47·00	85·46·15	85·46·37	2·10·50	10.54.17
11·00	86·57·50	86·51·01	86·51·25	1·04·48	10·48·00
0·00	86·05.30	86·04·45	86.05·07

6·00	87·10·18	87·09·25	87·09·41	0·43·51	10·57·75
0·00	86·05·26	86·04·40	86·05 03	1·04·38	10·46·33
11·00	89·33·05	89·32·17	89·32·43		
17·00*	88·23·10	88.22·27	88·22·48	2·10·05	10·40·83
23·00	87·22·39	87·21·59	87·22·16	1·00·32	10·05·00
28·00	86·28·22	86·27·44	86·28·03	0·54·13	10·50·60
23·00	87·22·52	87·22·08	87·22·30	0·54·27	10·53·40

∴ Rejecting the two observations marked with an asterisk as evidently wrong, the mean of the remainder is

$$10'50''99 = 651''$$

Hence the smallest possible reading is $\frac{651''}{100} = {}''6{\cdot}5$ and therefore any single pair of the above readings would have given a result sufficiently accurate. It appears also that the divisions in the scale are all accurately cut within the error of observation of the magnetic force, but that the scale divisions between 0·00 and 6·00 are inaccurate, being a little smaller than the mean.

The Diameter of Wheel No. 12, was determined by Keru Luximon. He turned the platina wire, with which the wheel is to be suspended several times round the wheel, and then measured the whole length of several circumferences in the following manner: The wheel A. W. B. was fixed in a wooden rod A. B. H. with its axle in C. The wire D.A.W.B.F.E was held tort at the two ends D. and E., a knot having been made as a mark at F. and the wire was passed over the wheel. As the wheel made a revolution, a point H. opposite to F. was marked off on the rod. Thus the length of ten circumferences was found 19·310 inches, which we presume to be quite correct from the accuracy of the measurements along the rod, as the point was successively marked off. Hence one circumference = 1·9310 inches; and the diameter = ·61465 inch.

3. The *interval of wires above* was measured 0·62985 of an inch.

4. *Length of line of suspension* found to be 30·33 inches.

5. The weight of the Magnet, the Collimator with stirrup and wheel together, equal to 7050 grains.

6. Hence,

$$G = w \frac{a \times b}{l} = 7050 \frac{0{\cdot}61465 \times {\cdot}062985}{30{\cdot}33} gi$$

7. The preliminary adjustments performed as usual and ultimately.

Torsion ⊙	Scale Reading	
68°27′	....	Plane of detorsion coinciding with the Magnetic Meridian.
338·28′	12·09	Weight attached.
266·03	12·55	Magnet suspended and North end to the West by which increase of force became denoted by increase of readings.
265·59	12·16	Ditto .....

$$\therefore v = 72° 29'$$

8. Since one division of the scale = 651″

$$\therefore a = 651'' \times {\cdot}0000483 = 0.00031443$$

$$\therefore k = a \cot v = 0.00099621$$

9. mX = G *sin* 72°29′ = 85.33 in grains and inches.

mX = 7·152 in grains and feet.

mX = 14119·20377 in millimetres and millegrammes.

10. By taking out the Magnet from the Large Declination Magnetometer, it appeared that ·027 requires to be added to the scale reading of the horizontal force for the effect of the Large Declinometer.

The above co-efficient is that which is to be used until Feb. 2^d 22^h; when it was necessary to obtain a new position for the Magnet, whose readings had now become nearly at the extremity of the scale. In the usual method of approximation it was found that

When the torsion ⊙ marked 66°38′

The reading was $\left\{\begin{matrix}4.42\\4.39\end{matrix}\right\}$ when the $\left\{\begin{matrix}\text{magnet}\\\text{weight}\end{matrix}\right\}$ was suspended.

∴ When the torsion circle marked 66°38′, the plane of detorsion coincided as near as possibly with the Magnetic Meridian ∴ When the torsion ⊙ marked 336°38′ the plane of detorsion would be perpendicular to the Magnetic Meridian at 18^h Göttingen time or a little earlier.

Now $tan\ v = \frac{a}{k} = \frac{0.00031443}{k}$

If then $k = .001$

$v = 72°21'$

and therefore in order to make $k = .001$ the reading of the torsion circle must be $= 336°38' - 72°21' = 264°17'$ when the Magnet is made perpendicular to the Magnetic Meridian. The torsion circle then reading 336°38′ and the weight being attached the readings of the telescope were

13·12
8·58
13·10 at 18h 5m G. M. T.
8·60

The true reading then was 10.845 when the plane of detorsion was perpendicular to the Magnetic Meridian. The torsion circle then being turned to 264°17′ it was necessary to obtain the same reading for the Magnet when perpendicular to the Magnetic Meridian in order that $k = .001$. This could be affected only by turning the micrometer, and thereby altering the interval of the threads above. After eight approximations, the results were

Time.	Mean Reading of Telescope.	Micrometer Reading	Thermometer.
20h 34m	10·59	63·0	80°3
20h 35m	10·91	62·0	

The instrument was left in these adjustments until the end of the year. From the 2nd February therefore to the end of the year

$$k = .001$$

May 1d. 18h. The readings having become very low, some fault in the instrument was suspected. Serjeant Dunn found a mass of cobweb at the bottom of the glass tube near the stirrup. On their removal, the reading became 14.480, which is nearly the same as that on the 31st March.

May 30d. 23h. 28m. Another cobweb was found by Keru Luximon. After its removal, the reading increased from 11.700 to 12.660.

June 10d. 15h. All the Magnetometers were vibrating.

July 21d. 15h. The wire of the Telescope had snapped.

17h The observation was taken 10m after the time.

Small Horizontal Force Magnetometer,

is of exactly the same description as the Bifilar, described in Lieut. Riddle's Instructions.

On the completion of the Small Observatory, it was set up and all the adjustments made by Keru Luximon and Serjeant Dunn. The notation in the following paragraphs is the same as that used by Lieut. Riddle.

August 6th 1845—The suspension tube attached and the instrument placed on its stand, resting on a bed of white lead cement, cemented to a block of wood four feet high; the level of the torsion circle adjusted by means of the plummet, which, when hanging freely quite in the centre of the suspension tube, indicated that the torsion circle is right. The instrument then retained in the required position for a sufficient length of time to allow the cement to set partially and prevent the level from changing. The sides of the box were placed at right angles to the line joining the centres of two blocks, coinciding nearly in this case with the Magnetic Meridian.

The Reading Telescope was fixed on the top of the stand, so that the prolongation of its axis passed through the centre of the mirror; this was done by increasing the distance of the eye piece from the object glass, and viewing the plummet, hung instead of the mirror, exactly on the central wire.

August 9th. The cement being nearly dry, the Magnet was suspended by a single thread of two fibres, the torsion having been previously taken out. The telescope with the scale attached above it was fixed so as to point nearly to the middle of the scale. Reading 21·5.

The suspended Magnet is a hollow cylinder, marked H. 36. Its length is 2·99 inches; its external diameter 0·30, and its internal is 0·24.

The distance from the face of the mirror to the scale $+\frac{1}{2}$ thickness of the mirror was found to be 62·2 inches.

The azimuth and the inclination of the mirror were previouly adjusted so as to reflect the divisons of the scale into the field of view.

Angular value of one division of the scale determined

$$a = 3437{\cdot}75 \times \frac{l}{2r} = 3437{\cdot}75 \times \frac{0{\cdot}2}{2 \times 62{\cdot}2} = \frac{3437{\cdot}75}{622} = 5{\cdot}53 \text{ in arc}$$

$\therefore$ a in parts of radius $= 0{\cdot}00161$

The adjustments were performed in order to bring the Magnet perpendicular to the meridian and to determine the value of k.; but the results not being satisfactory the adjustments were renewed as follows:—

August 22nd 1845—The Magnet and the double thread were removed and the weight suspended to a single thread. Torsion was taken out and the Magnet suspended in the plane of the meridian, the mirror turned in azimuth and reading of the scale found to be 18·45.

Time of one vibration, with single thread determined, arc of vibration being within 1.°

Number of Vibr.	Time.	Difference	Time of 300 Vibrations.	
	h. m. s.	m. s.

30	22·57·40·7	0·23·8	11·49·5	
40	22·58·04.5	0·23·5		$\therefore t = \frac{709^s \cdot 5}{300} = 2^s \cdot 365$
50	22·58·28.0	1·58·2	$=709^s \cdot 5$	
100	23·01·26·2	3·56·3		
200	23· 4·22·5	3·56·5		
300	23· 8·19·0			

Angular value of v, calculated for the co-efficient of reduction $= 0{\cdot}001$

$\text{Cot } v = a\kappa = 0{\cdot}00161 \times 0{\cdot}001$

$\therefore v = 58°08'$

The co-efficient of torsion was determined in the usual way by turning the torsion pin 90° on either side, and seeing the difference which this makes in the reading of the scale.

Circle.		Scale.	
Readings.	Difference.	Readings.	Difference.
°			
6		27·92	
96	90	28·05	0·13
276	180	27·72	0·33
06	90	27·91	0·19

Mean 0·16 difference for 90°

in arc 0′·9

$$\therefore \frac{H}{F} = \frac{u}{w - u} = \frac{0{\cdot}9}{5399{\cdot}1} = 0{\cdot}000106$$

$$\therefore \text{Coefficient of torsion} = 1 + \frac{H}{F} = 1{\cdot}000106$$

The time of one vibration of the Magnet when hung by the double thread was then calculated by the formulæ.

$$t' = \sqrt{t^2 \frac{sin\ \ v}{1 + sin\ v}}$$

$$= \sqrt{(2{\cdot}365)^2 \frac{sin\,(58°{\cdot}08)}{1 + sin\,(58°{\cdot}08)}\ 1{\cdot}000106}$$

$$= \sqrt{5{\cdot}5938 \times 1{\cdot}000106 \times \frac{sin\ (58°{\cdot}08)}{1 + sin\,(58°{\cdot}08'}}$$

$$= 1^s{\cdot}603$$

The Magnet was then supended by a double thread of two fibres (the mirror not being touched in the slightest degree by the hand, or allowed to come in contact with the

sides of the box); and the circle turned until the Magnet rested nearly in the Magnetic Meridian.

The torsion circle was further turned until the Magnet was very approximately in the meridian.

Readings.		
Torsion ⊙	Scale.	
°		
78·00	15·95	
78·25	17·80	
78·30	18·40	which is near enough.

The Magnet was now vibrated and the time of one vibration determined.

No. of Vibrations.	Time.	Difference.	
	h. m. s.	m. s.	
0	23·49·41·5	0·16·0	
10	23·49·57·5	0·16.0	
20	23·50·13·5	0·15·8	
30	23·50·29·3	0·15·7	$\therefore t' = \frac{159^s \cdot 1}{100} = 1^s \cdot 591$ which is a little too small.
40	23·50·45·0	0·16·0	
50	23·51·01·0	1·19·6	
100	23·52·20·6		

The difference between the calculated and observed values of t' shewed that the interval of the threads was not right. This interval was decreased a little and the Magnet again vibrated, reading of the scale 17·47.

No. of Vibrations.	Time.	Difference.	
	h. m. s.	m. s.	
0	0.00·46·0	1·19·5	
50	0· 2·05·5	1·19·0	$\therefore$ ● $= \frac{158 \cdot 5}{100} = 1^s \cdot 585$ a quantity still smaller.
100	0· 3·24·5		

The interval of the threads was now increased a little, and the Magnet again vibrated; the reading of the scale was found altered; the Magnet coincided with the meridian nearly, and reading of the torsion circle=78°35′

No. of Vibrations.	Time.	Difference.	
	h. m. s.	m. s.

40	0·18·24·0	0·16	$\therefore t' = \frac{160 \cdot 0}{100} = 1^s 600$ very near the required time.
50	0·18·40·0	1·20	
100	0·20·00·0		

The interval still increased a little, altered scale made to read 18·5 by turning the torsion circle to 70°40′ and the Magnet again coincided with the meridian, when the vibrations in this position were as below.

No. of Vibrations.	Times.	Differences.	
	h. m. s.	m. s.	
0	0·23·15·0	0·16·0	
10	0·23·31·0	0·16.0	
20	0·23·47·0	0·16·0	
30	0·24·03·0	0·19·0	$\therefore t' = \frac{480^s \cdot 5}{300} = 1^s \cdot 6017$
40	0·24·18·0	0·16·3	
50	0·24·35·3	1·20·2	
100	0·25·35.5	2·40·0	
200	0·28·35·5	2·40·0	
300	0·31·15·5		

From this last value of t', the angle v and the value of t'', was calculated.

$$\sin v = \frac{t'^2}{t^2 - t'^2} = \frac{(1\cdot6017)^2}{5\cdot5938 - (1\cdot6017)^2} = \frac{2^s\cdot5653}{5\cdot5938 - 2\cdot5653} = \frac{2\cdot5653}{3\cdot0285}$$

$$\therefore v = 57°54'$$

$$t'' = \sqrt{\frac{2}{\cot v}} = \sqrt{\frac{5\cdot5938}{\cot (87°54')}} = 2^s\cdot986$$

The torsion circle turned through angle of 30° + 57°54′=147°54′ (from 78°40′ to 290°46) in the direction in which the north end of the Magnet will be towards the west and the increasing readings will denote an increase of force.

The mirror was turned, withont stretching the thread, until the division about the middle of the scale was on the middle wire of the reading telescope. Reading 24.80.

The Magnet vibrated and the vibrations taken.

No. of Vibrations.	Times.	Differences.	
	h. m. s.	m. s.	
0	1·21·36·5	4·55·0	
100	1·26·31·5	2·28·0	$\therefore t'' = \frac{589\cdot5}{200} = 2\cdot952$
150	1·28·59·5	2·26·5	
200	1·31·26·0		

The calculated and observed t'' differing very much, the torsion circle was turned backwards, and the vibrations of the Magnet taken when the torsion circle read 289°46.

No. of Vibrations.	Times.	Differences.	
	h. m. s.	m. s.	
0	1·39·08·0	0·29·7	
10	1·39·37·7	0·29·8	
20	1·40·07·5	0·30·0	
30	1.40·37·5	0·30·0	$\therefore t' = \frac{896\cdot5}{300} = 2\cdot988$
40	1·41·07·5	0·29·8	
50	1·41·37·3	2·29·7	
100	1·44·07·0	4·58·7	
200	1.49·05·7	4·58·8	
300	1·54·04·5		

The difference between the observed and calculated values of t'' may have been produced by not being careful enough in turning the plane of the mirror not to stretch the double thread.

Reading of the scale at $2^h\ 07^m$ 22d August 1845. G.M.T.

Readings.	Mean.	Temp.
16·20 14·60 16·20	15·400	81°0

Calculation of the value of k for the Small Horizontal Force Magnet.

$$k = a\,\frac{t^2}{t''^2} = \frac{5^s\cdot 5938}{(2\cdot 988)^2} \times 0\cdot 00161 = 0\cdot 001007$$

Increasing numbers denote an increasing force.

Jan. $19^d\ 0^h$ A carriage coming near the observatory caused large vibrations.

Feb. 2^d The instrument required adjustments for the same reason as the large instrument. In performing them, the box was disturbed; and consequently it was necessary to refix it and re-perform the adjustments which were recommenced.

Feb. 6^d In order to obtain $k = \cdot 001$, it is necessary to take

$$v = 58°03'$$

now $t = 2^s.391$

and torsion force $= 1.00074$

$$\therefore t' = \sqrt{t^2\,\frac{\sin v}{1+\sin v}} = 1^s\cdot 619$$

Again by observation with double thread

$t' = 1^s 54$ and torsion circle read 192°50′

The interval of the threads was therefore increased, and

$t' = 1^s 630$ and torsion circle read 191°01′

The interval was decreased, and

$t' = 1^s 6193$ and torsion circle read 190°40′

Hence,

$$\sin v = \frac{t'^2}{t^2 - t'^2} = \sin 58°03'$$

$$\text{and } t' = \sqrt{\frac{t^2}{\cot v}} = 3^s\cdot 028$$

The torsion circle was now turned 148°03′ (from 190°40′ to 42°37′) in the direction in which the north end of the Magnet will be towards the west, and the increasing readings will denote increasing force; and by 100 vibrations

$t'' = 3^s\cdot 023$

Since this is too small the torsion circle was moved to 42°25′; and now

$t'' = 3^s\cdot 027$

The mean reading of the scale was 27·310 and the temperature 84°·2 at the time when the determination was completed.

Therefore from the 6th Feb. to 29th May,

$$k = a\frac{t^2}{t''^2} = 0{\cdot}001003$$

March, 5^d 0^h. The instrument shaken.

June, 22^d 22^h 30^m. All the small instruments having been fixed on stone pillars and being now ready for adjustment, the Magnet was removed, and its support a single thread of two filaments was stretched by the brass weight until its torsion was destroyed.

22^h 40^m. The Magnet replaced, so that the scale was distinctly seen in the telescope.

$$\text{Since } \frac{l}{2r} = \frac{0{\cdot}20}{2\times 62{\cdot}75}$$

$$\therefore a = \frac{l}{2r} \times 3437{\cdot}75 \times {\cdot}0002909 = 0{\cdot}0001593$$

Let $k = 0{\cdot}001$

then $v = 57°53'$

The coefficient of torsion determined

$$1 + \frac{H}{F} = 1{\cdot}000568$$

Again by vibrations

$$t = 2^s414$$

$\therefore$ by calculation

$t' = 1^s635$, and the reading of the scale was 25·25

The Magnet being now supported by the double thread, the torsion circle was further turned until the Magnet was very approximately in the meridian.

Time.	Readings.		
	Torsion ⊙	Scale.	
h. m.	° ′		
18·18	29·35	29·00	
18·21	28·55	25·60	which is near enough.

The Magnet being now vibrated $t' = 1{\cdot}617$.

Interval of threads.	Readings.		t'	Number of Vibrations.
	Torsion ⊙	Scale.		
	° ′			
Increased.	28·55	23·65	1°610	100

$\therefore k = a\frac{t^2}{t'^2} = 0{\cdot}000981$ and the reading of the scale was 28·54, temp. = 82°1 1846 June 23^{d} 20^{h} 45^{m}.

Determination of the effect of changes of temperature upon the Magnets used in the Horizontal Force Magnetometers.

The co-efficient of temperature is considered = 0, on account of the reasons given in the introduction for 1845, pages XVIII—XLVIII.

Variation of Magnetism in the Magnets.

In the results of 1845, it had been shewn that the only hope of discovering the changes, which take place during the year in the horizontal force, rested with the Horizontal Force Magnetometer. Nothing however can be deduced from this instrument, unless the changes of magnetism in the bar Magnet could be ascertained. It was convenient to attempt the ascertainment of this by an indirect method, which did not indeed give the desired results, but which shews limits within which it may be presumed that the magnetism of a bar Magnet varies.

For this purpose it was determined to ascertain the changes of magnetism in two bar Magnets, exactly similar in weight and dimensions to those in the Large Declinometers. One of these is distinguished by being divided into inches; the other is marked No. III.

The bar No. III was from the 24th August until the end of October, in the open air but protected from weather by unmagnetic coverings, under some trees, near the Altitude and Azimuth Observatory, and at some distance from any Magnets or iron work. It was placed perpendicular to the magnetic meridian with its north end west, and was therefore in the same position as the bar in the Large Horizontal Force Magnetometer. At intervals it was taken to the Observatory; when care was taken to keep it covered

from the rays of the sun and to preserve its perpendicularity to the meridian and its horizontality. In the Observatory it was used to deflect the small Magnet used for absolute determinations.

The precautions abovementioned were deranged in no case but one on the 9th September, when, in bringing the bar into the Observatory, it was dropt; it fell however horizontal.

Deflections of C 25 caused by the bar Magnet.

$$(s\,S')^3 = \left\{(R-L)^2 + l^2 + 2\,l\,(R-L)\,\sin u\right\}^{\frac{3}{2}}$$

$$(n\,S')^3 = \left\{(R+L)^2 + l^2 + 2\,l\,(R+L)\,\sin u\right\}^{\frac{3}{2}}$$

$$(n\,N')^3 = \left\{(R+L)^2 + l^2 - 2\,l\,(R+L)\,\sin nu\right\}^{\frac{3}{2}}$$

In the present case $R-L = 4$ feet $- 7\frac{1}{2}$ inches $= 3{\cdot}375$

$$l = 0{\cdot}2627$$

$$\therefore \frac{l}{R-L} = 0{\cdot}0778$$

the greatest value of $u = 1°27'10''$

$\therefore$ The greatest $\sin u = 0{\cdot}0253$

Now let $\frac{2X}{M}\tan u = a$ $\therefore$ $\log M = \log 2X + \log \tan u - \log a$; but $\log 2X$ can be accurately ascertained (Results 1845) only to the fourth place of decimals $\therefore$ $\log a$ need be accurate only to the same number of places. But

$$\frac{R-L}{(s\,N')^3} = \frac{1}{(R-L)^2}\left\{1 + \frac{l^2}{(R-L)^2} - \frac{2\,l}{R\,L}\sin u\right\}^{\frac{3}{2}}$$

$$= \frac{1}{(R-L)^2}\left\{1 + 3\,\frac{l}{R-L}\sin u - \frac{3}{2}\,\frac{l^2}{(R-L)^2}\right\}$$ which is accurate in the extreme case to four places of decimals by the above numerical values.

and $\frac{R-L}{(S's)^3} = \frac{1}{(R-L)^2}\left\{1 - 3\,\frac{l}{R-L} - \frac{3}{2}\,\frac{l^2}{(R-L)^2}\right\}$ for the same reason.

$$\therefore \left(R-L\right)\left\{\frac{1}{(sN')^3} + \frac{1}{(s\,S')^3}\right\} = \frac{1}{(R-L)^2}\left\{1 - 3\,\frac{l^2}{(R-L)^2}\right\}$$

$$\text{and } \left(R + L\right)\left\{\frac{1}{(n\,S')^3} + \frac{1}{(n\,N')^3}\right\} = \frac{1}{(R + L)^3}\left\{1 + 3\,\frac{l^2}{(R - L)^2}\right\}$$

Hence a is independent of u

$$\therefore \frac{\delta M}{M} = \frac{\delta X}{X} + 2 \operatorname{cosec} 2u\ \delta u$$

Now the variation of the deflection between August 24th and October 30th $= 3{\cdot}12 - 3{\cdot}07 = 0{\cdot}05$ scale reading $= 1'.40$.

$$\therefore -\delta u = \frac{1'.40}{180^\circ}\,\pi = {\cdot}00407$$

$$\text{and cosec } 2u = 19{\cdot}7$$

$$\therefore \frac{\delta M}{M} = \frac{\delta X}{X} - {\cdot}1603$$

now X about August 24th and 31st was 7·885 and about the end of October was not less than 7·784 when it was diminishing $\therefore \delta X = -0{\cdot}011$ at most

$$\therefore \frac{\delta X}{X} = -0{\cdot}001 \text{ at most}$$

Hence the magnetism of the bar must have diminished by at least $M \times {\cdot}160$. But $2M$ seems by the above observations to have been very nearly $= 10$; and therefore the diminution of magnetism in the bar was possibly

0·80

Or supposing even that δu may have been taken at double its true value, the diminution will yet be

0·40

The loss therefore of magnetism in these large Magnets seems very rapid, and fully accounts for the discrepancies of results between the absolute determinations and the Magnetometers.

The divided bar Magnet was kept in a hut, erected at a very considerable distance from any other building in the Observatory compound. It was placed in the meridian with its north end north until the 7th October. It was expected that in this position the magnetism would increase. Afterwards the north end was turned to the south. The same precautions, and the same method of trying its magnetism was used as for No. III; and the following are some of the observations:

Deflections caused by the divided bar on C 25in declinometer, No. III.

Distance of centres of Magnets.	Differences of readings when the bar was away and when its north end was															
	W.	E.	W.	E.	W.	E.	W.	E.	W.	E.	W.	E.	W.	E.	W.	E.

Date.....	Aug. 23		Aug. 31		Sep. 9		Sep. 16		Sep. 30		Oct. 7		Oct. 14			

The difference of readings north end W and E is owing to the centre being wrongly cut; for it is about 0·05 inch too near the south end.

These experiments further prove that in whatever position a Magnet is placed, its force is continually diminishing at a rapid rate for large bars.

DIURNAL CHANGES OF THE VERTICAL FORCE.

These have been observed with a Balance Magnetometer by Robinson. But as this instrument has been fully described in the *Directions of the Royal Society*, and in an *Account of the Magnetical Observatory of Dublin* by Professor Lloyd, and as there is no peculiarity in our instrument, it is unnecessary for me to describe it.

September 14th 1845. On examining the registers I concluded that the previous observations could not be expected to yield any results; and they would not have been published, had I not thought that some negative argument might be derived from them. The cause of its unsatisfactory working appeared to be in the small value of the absolute vertical force of the earth in comparison with that of the horizontal force, and that consequently the knife edges were continually drawn out of their proper position into one at an angle with the meridian. On examination I found that such in fact was the case.

Further, the knife edges had become rusty and notched, and the friction consequently being great the free motion of the needle on its axle had been greatly impeded.

The Magnet was therefore carefully freed from dust by emery and oil, rubbed on with soft leather. The knife edges were taken out and sharpened. Serjeant Dunn in doing this took the opportunity of rendering the balance more sensible than it had been before, by bringing the plane containing the centre of gravity of the unloaded instrument and the edge of the support, perpendicular to the line joining the crosses of the needle.

Serjeant Dunn then performed the following adjustments:

The level of the base was examined and found not to have been disturbed; the brass needle was then placed on the agate planes, and the fixed wires of the microscopes adjusted to the same horizontal line, in the usual manner.

The correctness of the micrometers was next determined:—the brass needle *carrying*

a scale on each end, was placed on the agate planes, and the *value of each turn of the micrometer heads* found to be as follows:—

South Microscope.

Standard Scale.	Micrometer.
10′	1·44·0
20	4·02·8
30	6·04·2
40	8·02·5
50	9·32·0

North Microscope.

Standard Scale.	Micrometer.
10′	2·00·0
20	3·48·5
30	6·02.5
40	8·06.5
50	10·10·0

The irregularities of these readings were found to proceed from a fault in the run of the microscope screws.

The Brass boxes were taken out and the run of the screws adjusted; they were then replaced, and the eye pieces of the Micrometers drawn out until distinct vision of the wires were obtained. The Micrometer heads were now turned, and the readings observed to be:—

South Microscope.

Standard Scale.	Micrometer.
10′	2·00·0
20	4·00·6
30	6·01·0
40	7·48·6
50	10·08·0

North Microscope.

Standard Scale.	Micrometer.
10′	2·00·0
20	3·49·0
30	5·49·8
40	7·49·8
50	9·38·8

These readings shew, that in order to make the turns of the Micrometer heads agree exactly with the divisions on the scale, it was necessary to increase the distance between the lines of the needle and the object-glass of the south Microscope, and to decrease the distance between the limb and the object glass of the north Miscroscope. This was accordingly done for the S. Microscope, by moving the small collar screw of the object-glass towards the limb, and then moving the whole body of the Microscope towards the limb until distinct vision was obtained, and vice versa for the N. Microscope. The divisions of the scale are 10′ distant from one another; and after the foregoing adjustments, two revolutions of each Micrometer head coincided exactly with each

division of the scale: the adjustment was completed, and the reading found to be:—

Readings.	Mean.	Temper.
S — 3·47·5 N + 0·11·0	1·43·20	88°0

The adjustments of the needle were then made in the usual manner.

Feb. 19d. 0h. The sun's rays affected the observations.

20d. 11h. The third vibration was too great.

March 5d. 14h. The observation was made 20m. after the time.

April 10d. 0h. The instrument was cleaned and a new wire put into the north microscope.

Feb. 24d. 4h. 30m. Since it was suspected that the light of the lamps brought before the glass face of the instrument, and also the changes of day light affected the readings in a similar although less degree than solar light, a paper shade blackened internally was put over the glass face. Two holes were made to let light upon the crosses, and one to read the Thermometer. Two lights were placed before the instrument to illumine the crosses.

The lights were tumblers with oil; and the wicks of cotton on brick supports. To ascertain whether any part of this apparatus was Magnetic, the following consecutive readings of the Large Horizontal Force Magnetometer were made:

12·77
13·10
12·72 } the light at distance.

13·10
12·78
13·10 } the light very near the west end of the bar Magnet.

12·76
13·10 } the light again removed.

March 5d. 14h. The observation made 20m. after the time.

April 10d. 0h. The instrument was cleaned, and a new wire put into the north microscope.

May 14d. 24h. A spider caught in the Magnetometer. He had caused a great disturbance.

May 20d. 0h. The Magnet was cleaned.

28d. 5h A wrong reading, owing (it is supposed) to a cobweb; for after being

vibrated, the reading returned to the position which it should have taken consistently with the previous observations.

June $4^d.$, $0^h.$, $1^h.$, $14^h.$ Lost on account of experiments.

$10^d.$ $15^h.$ All the Magnetometers vibrating.

Aug. $1^d.$ $19^h.$ The observations having been unsatisfactory for the last week, the needle was taken out and cleaned. Without altering the fixed wires of the microscopes, the other adjustments were re-completed by Keru Luxamon.

Oct. $4^d.$ $19^h.$ The knife edge, being rusty and jagged, was cleaned and sharpened and the instrument re-adjusted.

Oct. $18^d.$ $9^h.$ The Magnet vibrating very much.

$23^d.$ $4^h.$ The time occupied in checking the vibrations caused the observations to be put off until $10^m.$

Oct. $25^d.$ $23^h.$ Reading at $23^h.$ $40^m.$ $4°32'20.$ In order to ascertain the cause of the change in the last two hours, Sergeant Dunn opened the box and found many ants about the instrument although he found none on the Magnet. The marble base and the box both within and without was cleaned; and the box replaced. During this examination, he was careful not to disturb the Magnet. After the replacement of the box, the reading was $-4°.46'.22.$

Oct. $20^d.$ $23^h.$ A spider was caught in the Magnetometer.

Nov. $10^d.$ $21^h.$ The door near the Magnetometer was open.

Nov. $19^d.$ $16^h.$
Dec. $16^d.$ $23^h.$
—— $17^d.$ $20^h.$
} Observations interrupted by experiments.

Dec. $21^d.$ $0^h.$ The paper screen had been taken off.

$20^h.$ But was replaced.

$22^d.$ $20^h.$ The Magnet was raised and again lowered on the agate planes.

$30^d.$ $20^h.$ The instrument re-adjusted.

Effect of Temperature on the Magnet.

The experiments to determine this are given in the introduction for 1845; and the correction is presumed to be $= 0.$

Effect of Solar white light upon the Magnet.

As the glass face of the Magnetometer is before a window, which, although generally closed by venetians, might occasionally be opened, I thought it necessary to de-

termine the effect of solar light.

50·00		+ 4·36·0	+ 0·11· 0		

Three readings are necessary.

Let S C N be the needle of the vertical force Magnetometer, S being the south and N the north pole, and C the centre. Let P be the point of suspension. Suppose that when SCN is horizontal, PC is vertical. Join PN, PS. Then $\angle$ PSC = $\angle$ PNC; and let each = γ. Let PRT be the horizontal line through P, cutting the Magnet in R. Let G be the centre of gravity of the whole apparatus which vibrates with the needle. Then by the construction of the instrument G is below P, and on the south of C. Join GP, and produce GP to Q in SCN. Let CQP = ϵ

Let $\angle$ IPN = α''

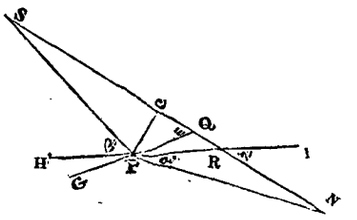
$\angle$ SPH = β''

$\angle$ IRN = η'

$\therefore \alpha'' = \eta' - \gamma$

$\beta'' = \eta' + \gamma$

$\therefore \eta' = \frac{\alpha'' + \beta''}{2}$



If the crosses were at N and S, or in the same line as N and S, α'' and β'' would be the readings of the north and south Micrometers. If this be the case, the readings of the Magnet will be unaltered when the faces of the needle are reversed. If they are not in the same line as N and S after reversal, the reading will have changed and half the difference of the readings will be the difference of the angles made by the magnetic axis and the axis of the crosses respectively. December 19^d. and 20^d. it was found that the difference of these angles in the Bombay instrument = 6.'8, and the position of the magnetic axis and the cross-axis is such that the north pole is above the north cross. Consequently α' and β' being the readings of the crosses when the axis is steady,

$$\eta' = \frac{\alpha' + \beta'}{2} - 6'.8$$

Since, however, the needle is always vibrating, the readings α' and β' are never made. Let however the reading α be taken, when the north cross is moving from the horizontal line, at the end of a vibration = $2v$; then $\alpha = \alpha' + v$, if the vibration is uniform on each side of the true position of equilibrium; and let β be read at the other end of the same vibration; then $\beta = \beta' - v$.

$$\therefore \frac{\alpha + \beta}{2} = \frac{\alpha' - \beta'}{2}$$

$$\therefore \eta = \frac{\alpha + \beta}{2}$$

If then the vibration is uniform, two readings are sufficient; if not, at least three vibrations must be taken, and the place of the true position of equilibrium determined as for the other Magnetometers by the method of Gaus's. Until Jan. 13^d. 15^h. two ob-

servations only were made according to the usual manner; after which I directed three observations of each cross to be observed. Keru Luxamon however observing that this took up much time, and two observations of the north end and one of the south would effect the same object, this modification of my plan was followed from Jan. 16d. 20h. to the end of the year. And a_1 a_2 being the observations of the north cross, and β that of the south cross, the published observations are,

$$H = \frac{a_1 + 2\beta_1 + a_2}{4}$$

Whilst the six observations were made the observers misunderstood my directions, and did not always take care to observe the extreme reading. These observations therefore are not to be depended upon.

The following table contains the the values of $a_1 \sim a_2$ at every hour Bombay mean time from 16th Jan. to 24th Feb.

The hours which are left blank are those when no observation was taken; those which are marked with — are those when $a_1 \sim a_2 = 0$.

The value of $a_1 \sim a_2$ is therefore very considerable at night during the interval from 16d. Jan. to 24d. Feb; and it is very inconsiderable during the day. But the projections (Plate 3) prove that the magnetism of the earth varies most between 20h. and 4h. B. M. T. Moreover, currents of air are more likely to have been troublesome during the day than during the night; for at the latter time, the observers kept the Observatory as much as possible closed for their own personal comfort. The difference therefore was

most probably owing to a change of magnetism in the needle. Now it has been shewn that the sun's light increases the magnetism of the needle; and it was therefore imagined that the light of the lamps might be the cause of a change of magnetism. For between each two observations, for the space of nearly an hour, the Magnet was in total darkness, and therefore radiating away its magnetism, which all undisturbed magnets seem to do according to some general law; at the end of that time the observer used to bring his lamp before the glass face, and the Magnet was illumined in its whole length. If then artificial light has the same effect as solar light, the lamp light would instantaneously augment the magnetism of the needle, which would then vibrate into a new position of equilibrium.

In order to test the truth of this theory, the face of the Magnetometer was covered with a sheet of paper blackened within, so that the interior of the box was in a state of perpetual darkness. Through this screen, light was admitted into the box by three perforations; one illumined each cross, and one the Thermometer about the ordinary readings of the stem. Thus, it was supposed that no light would fall on the Magnet itself. But in order that this might be of no consequence, even should any sensible light fall on it, two lights were kept constantly burning, one before each cross, in order that the same light always illumining the Magnet, the same amount of magnetism might be caused by it. The following table contains all the values of $\alpha_1 \sim \alpha_2$ when $\alpha_1 \sim \alpha_2$ was not equal to nought between Feb. 25 and May 28.

It thus appears that the change of vibrations at night almost entirely ceased from the time that the screen was affixed. The vibrations, which subsequently occurred, were no more than might be expected from accidental currents of air, accidental neighbourhood of iron, or accidental induction.

Hence it seems fair to conclude that the *magnetism of the needle was augmented during the night by the lamp until the screen was used.* And, moreover, since it has been shewn that the sun's *reflected* light augments magnetism, the irregularity of $a_1 \sim a_2$ during the day previously to the 24th Feb. is to be explained by the irregularity of the light within the Observatory; and therefore *the magnetism of the needle has been irregularly augmented during the day by the day light until the screen was used.*

Corrections therefore to former Observations may be necessary not only on account of the omission of a third reading but also on account of these variations in the magnetism of the needle.

The coefficient of reduction.

Let W be the weight of the Magnet.

d	distance from its centre of gravity to the point of suspension.	
$2l$	length of the needle.	
m	magnetic power of each pole.	When η' is the angle made by the axis of the needle with the horizon.
Y	the vertical force of the earth	
X	horizontal force of the earth	
D	inclination	

Hence (Dr. Lloyd's Report of the Magnetical Observatory of Dublin p. 47.)

$$2m\,Yl\cos\eta' - 2m\,Xl\sin\eta' = d\,W\cos(\varepsilon - \eta')$$

$$\therefore 2m\,l\cos\eta'.\,\delta Y - 2m\,l\sin\eta'\,\delta X + (2\,lY\cos\eta' - 2\,lX\sin\eta')\,\delta m = \{2m\,Yl\sin\eta' + 2m\,Xl\cos\eta' + d\,W\sin(\varepsilon-\eta')\}\delta\eta'$$

$$= \left\{\begin{array}{l} 2m\,Yl\sin\eta' \times 2m\,X\,l\cos\eta' \\ + \dfrac{\sin(\varepsilon-\eta')}{\cos(\varepsilon-\eta')}(2m\,Yl\cos\eta' - 2m\,Xl\cos\eta') \end{array}\right\}\delta\eta'$$

$$= 2m\,l\,\frac{Y\sin\varepsilon + X\cos\varepsilon}{\cos(\varepsilon-\eta')}\,\delta\eta'$$

$$\therefore \frac{\delta Y}{Y} = \cot D\tan\eta'\,\frac{\delta X}{X} + \frac{\tan\varepsilon + \cot D}{\cos\eta'}\,\frac{\cos 2}{\cos(\varepsilon-\eta')}\,\delta\eta' - (1 - \cot D\tan\eta')\,\frac{\delta m}{m}$$

In order then to calculate δY, ε must be known. In order to determine this the following method was used. Above the Magnetometer a frame work of wood was fixed. This frame work supported a grooved rod several feet long, so fixed that the groove might be exactly vertical, and its centre exactly over the centre of the vertical force magnet. A small Magnet was raised and lowered in this groove by means of a thread which passed over a pulley at the top of the groove, and the other end of which was managed by the observer's hand. This Magnet then deflected the vertical force needle; and the value of ε may be determined by these deflections.

For let R be distance between the centres of the two magnets; then the needle is in a position of equilibrium due to the action of the earth's magnetism, its own weight, and the attractions and repulsions of the deflector on its poles. Let then η be the angle which the axis of the needle makes with the Horizon; η', that which it would make, were the deflector removed. Let n and s be the poles of the deflector, and M its magnetism. Draw $s\mathrm{P}'$ and in $n\mathrm{P}$ perpendiculars to SN. The equation of equilibrium is, then,

$$-d\,\mathrm{W}\cos(\varepsilon-\eta)+2\,\mathrm{Y}l\,m\cos\eta-2\,\mathrm{X}l\,m\sin\eta+l\mathrm{M}\,m\left\{\frac{n\,\mathrm{P}}{(\mathrm{N}n)^3}-\frac{s\,\mathrm{P}'}{(\mathrm{S}\,n)^3}+\frac{n\,\mathrm{P}}{(\mathrm{N}\,s)^3}-\frac{s\,\mathrm{P}'}{(\mathrm{S}\,s)^3}\right\}=0$$

but $d\,\mathrm{W}\cos(\varepsilon-\eta')=2\,m\,\mathrm{Y}\,l\cos\eta'-2\,m\mathrm{X}l\sin\eta'$

$$\therefore\ 2\frac{\mathrm{Y}}{\mathrm{M}}\frac{\sin(\eta-\eta')}{\cos(\varepsilon-\eta')}\sin\varepsilon-2\frac{\mathrm{X}}{\mathrm{M}}\frac{\sin(\eta-\eta')}{\cos(\varepsilon-\eta)'}\cos\varepsilon=\frac{n\,\mathrm{P}}{(\mathrm{N}\,n)^3}-\frac{s\,\mathrm{P}'}{(\mathrm{S}\,n)^3}+\frac{n\,\mathrm{P}}{(\mathrm{N}\,s)^3}-\frac{s\,\mathrm{P}'}{(\mathrm{S}\,s)^3}$$

Let 2L be the length of the deflector

$$\therefore\frac{2\sin(\eta-\eta')}{\mathrm{M}\cos(\varepsilon-\eta')}\frac{\mathrm{Y}\sin\varepsilon+\mathrm{X}\cos\varepsilon}{\cos\eta}=(\mathrm{R}-\mathrm{L})\left[\left\{(\mathrm{R}-\mathrm{L})^2+l^2+2l(\mathrm{R}-\mathrm{L})\sin\eta\right\}^{-\frac{3}{2}}+\left\{(\mathrm{R}-\mathrm{L})^2+l^2+2l(\mathrm{R}-\mathrm{L})\sin\eta\right\}^{-\frac{3}{2}}\right]$$

$$-(\mathrm{R}+\mathrm{L})\left[\left\{(\mathrm{R}+\mathrm{L})^2+l^2+2l(\mathrm{R}+\mathrm{L})\sin\eta\right\}^{-\frac{3}{2}}+\left\{(\mathrm{R}+\mathrm{L})^2+l^2-2l(\mathrm{R}+\mathrm{L})\sin\eta\right\}^{-\frac{3}{2}}\right]$$

If $2l\,(\mathrm{R}-\mathrm{L})\sin\eta$ may be neglected in comparison with $(\mathrm{R}-\mathrm{L})^2+l^2$

$$\text{Let } 2\frac{\mathrm{R}-\mathrm{L}}{\left\{(\mathrm{R}-\mathrm{L})^2+l^2\right\}^{-\frac{3}{2}}}2\frac{\mathrm{R}+\mathrm{L}}{\left\{(\mathrm{R}+\mathrm{L})^2+l^2\right\}^{-\frac{3}{2}}}=\mathrm{Q}$$

$$\therefore\frac{2}{\mathrm{M}}\frac{\sin(\eta-\eta')}{\cos(\varepsilon-\eta')}\frac{\mathrm{Y}\sin\varepsilon-\mathrm{X}\cos\varepsilon}{\cos\eta}=\mathrm{Q}$$

$$\therefore\frac{2\mathrm{X}}{\mathrm{M}}\frac{\sin(\eta-\eta')}{\cos\eta\cos\eta'}\frac{\tan\mathrm{D}-\cot\varepsilon}{\tan\eta'+\cot\varepsilon}=\mathrm{Q}$$

$$\text{Let } \frac{\mathrm{QM}}{2\mathrm{X}}\frac{\cos\eta\cos\eta'}{\sin(\eta-\eta')}=\mathrm{B}$$

$$\therefore\frac{\tan\mathrm{D}-\cot\varepsilon}{\tan\eta'+\cot\varepsilon}=\mathrm{B}$$

$$\therefore\tan\varepsilon=\frac{1+\mathrm{B}}{\tan\mathrm{D}+\mathrm{B}\tan\eta'}$$

$$\text{and } \cot\mathrm{D}+\tan\varepsilon=\frac{2+\mathrm{B}+\mathrm{B}\cot\mathrm{D}\tan\eta'}{\tan\mathrm{D}+\mathrm{B}\tan\eta'}$$

And if the terms, in which $\tan\eta'$ is a factor, may be neglected

$$\tan\varepsilon=(1+\mathrm{B})\cot\mathrm{D}$$

$$\cot\mathrm{D}+\tan\varepsilon=(2+\mathrm{B})\cot\mathrm{D}$$

In order to ascertain the value of ϵ, the following observations have been made:

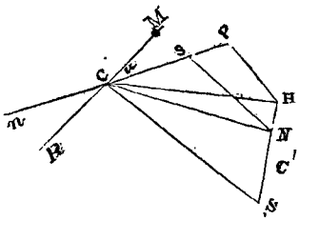
1846. In order to ascertain the value of M which is to be used in these experiments, it would not be correct to use that value which is obtained by the usual method of deflections in which the deflector is Horizontal; because when the Magnet is vertical, magnetism is induced and consequently the Magnet is stronger with its north end below, and weaker with its north end above, than in its usual position; consequently the values of *log* L M for I_{11} have been ascertained on the following principle and by the experiments now to be explained.



Let M C R be the magnetic meridian Horizontal line passing through *c*, the centre of *n* C *s* a Magnet which is free only to move round *c* in the Horizontal plane.

C H Horizontal and ⊥ to MCR

N S a Magnet fixed in the Horizontal plane CHS, so that SNH is ⊥ to CH.

Then n C s is attracted both by NS and the earth and consequently takes a position of rest making an angle MCP with the meridian.

Let $\angle$ MCP $= u$.

PH be $\perp$ to n C s P.

M .. the Magnetic power of N and also of S

m ..... n ..... s

$2l$ the length of n s

2L ..... N S

CH $=$ R

Let C′ be the centre of NS and HC′ $= x$

$\therefore$ the force exerted by N on $s = \frac{M\,m}{(N\,s)^2}$

$\therefore$ the effective part of this force in the Horizontal plane $= \frac{H\,s}{(N\,s)^3}\,M\,m$

$\therefore$ the effective force of N to turn s round $c = \frac{P\,H}{H\,S}\,\frac{H\,S}{(N\,s)^3}\,M\,m = \frac{R\,\cos u}{(N\,s)^3}\,Mm$

$\therefore$ the moment of N to turn s round $c = \frac{R\,l\,\cos u}{(N\,s)^3}\,M\,m$

and ..... N ..... n ..... $= \frac{R\,l\,\cos u}{(N\,n)^3}\,M\,m$

..... S ..... s ..... $= -\frac{R\,l\,\cos u}{(S\,s)^3}\,M\,m$

..... S ..... n ..... $= -\frac{R\,l\,\cos u}{(S\,n)^3}\,Mm$

..... X ..... s ..... $= -X\,m\,l\,\sin u$

..... X ..... n ..... $= -X\,m\,l\,\sin u$

$\therefore \frac{2X}{M\,R}\,\tan u = \frac{1}{(N\,s)^3} + \frac{1}{(N\,n)^3} - \frac{1}{(S\,s)^3} - \frac{1}{(S\,s)^3}$

also $(N\,s)^2 = (x - L)^2 + (s\,H)^2 = (x - L)^2 + R^2 + l^2 - 2\,l\,R\,\sin u$

$\therefore (N\,s)^{-3} = \{(x - L)^2 + R^2 + l^2 - 2\,l\,R\,\sin u\}^{-\frac{3}{2}}$

in like manner

$(N\,n)^{-3} = \{(x - L)^2 + R^2 + l^2 + 2\,l\,R\,\sin u\}^{-\frac{3}{2}}$

$(s\,S)^{-3} = \{(x + L)^2 + R^2 + l^2 - 2\,l\,R\,\sin u\}^{-\frac{3}{2}}$

$(S\,n)^{-3} = \{(x + L)^2 + R^2 + l^2 + 2\,l\,R\,\sin u\}^{-\frac{3}{2}}$

If then $2\,l\,\mathrm{R}\,\sin u$ is an inappreciable number

$$\frac{2\,\mathrm{X}\,\tan u}{\mathrm{M\,R}} = \frac{2}{(\mathrm{N}\,s)^3} - \frac{2}{(\mathrm{S}\,s)^3}$$

$$\therefore \frac{\mathrm{X}\,\tan u}{\mathrm{M\,R}} = \frac{1}{(\mathrm{N}\,s)^3} - \frac{1}{(\mathrm{S}\,s)^3}$$

$$\therefore \frac{\mathrm{X}\,\tan u}{\mathrm{M\,R}} = \left\{(x-\mathrm{L})^2 + \mathrm{R}^2 + l^2\right\}^{-\frac{3}{2}} - \left\{(x+\mathrm{L})^2 \times \mathrm{R}^2 + l^2\right\}^{-\frac{3}{2}}$$

$$= (x^2 + \mathrm{L}^2 + \mathrm{R}^2 + l^2)^{-\frac{3}{2}} \left(1 + \frac{3\,x\,\mathrm{L}}{x^2 + \mathrm{L}^2 + \mathrm{R}^2 + l^2} - \&c\right)$$

$$- (x^2 + \mathrm{L}^2 + \mathrm{R}^2 + l^2)^{-\frac{3}{2}} \left(1 - \frac{3\,x\,\mathrm{L}}{x^2 + \mathrm{L}^2 + \mathrm{R}^2 + l^2} - \&c\right)$$

$$= \frac{6\,x\,\mathrm{L}}{x^2 + \mathrm{L}^2 + \mathrm{R}^2 + l^2)^{\frac{5}{2}}} \text{ if } x^3\,\mathrm{L}^3 \text{ is inappreciable}$$

$$\therefore \mathrm{M\,L} = \frac{\mathrm{X}}{6\,\mathrm{R}\,x}(x^2 + \mathrm{L}^2 + l^2 + \mathrm{R}^2)^{-\frac{5}{2}}\,\tan u$$

Let $\frac{\mathrm{X}}{6\,\mathrm{R}\,x}(x^2 + \mathrm{L}^2 + l^2 + \mathrm{R}^2)^{-\frac{5}{2}} = \mathrm{X}_2$

$$\therefore \mathrm{M\,L} = \mathrm{X}_2\,\tan u$$

The Magnetism of I_{11} was accordingly ascertained by deflecting C_{1v}. A Horizontal line perpendicular to the Magnetic Meridian at the centre of C_{1v}. was carefully determined; and its Horizontality was determined by means of points in the Observatory walls, which points had been previously levelled by the surface of water communicating in flexible tubes. I_{11} was suspended from a moveable bar by a thread and pulley by which it could be brought to different heights above and below the plane of the deflected Magnet without any application of the hand to the deflector, and the thread was always in the vertical plane perpendicular to the Magnetic Meridian plane and passing through the centre of the deflected Magnet. The values of x were 0·1017,0·1434, and 0·1850 both above and below the Horizontal line. The Observations and results are exhibited in the following tables.

Date.	R.	Deflection in Scale.	Deflection in Arc.	*Log tan u*	*Log* X_2	*Log* L M. when the north end was uppermost.	*Log* L M. when the north end was lowered.

Unless errors of observation have been committed, much larger than can be supposed, it follows from these tables that the Magnetism of l_{II} when reversed continued to increase if the reversal was from the north end below to the north end above, although at the instant of reversal it was greatly diminished. And in like manner when the reversal was of a contrary nature, the Magnetism continued to diminish, although at the moment of reversal, it was greatly increased. These phenomena are consistent

with observations on induction; and cause much difficulty in determining L M for a vertical Magnet.

The values of $\eta - \eta'$ have also inconsistencies which are probably referable to the unascertained laws of induction. Pending therefore more complete determinations and more accurate knowledge, it seems expedient to make the following assumptions for the determination of B and ε.

For the observations between Dec. 9d. and Dec. 14d.

$log\ 2\ X = 1{\cdot}9992.$

$log\ L\,M = -\ 2{\cdot}87732.\ \therefore\ log\ M = 1{\cdot}87000.$

$\eta' - \eta = -\ 55'$; when R = 2 feet, and Q = 0·08443.

$\eta' - \eta = -\ 18'$; ..... 3 feet, ... 0·02772.

For the observations between Dec. 15d. and Dec. 17d.

L M = 0·1080 which is the value from the corrected values in the determination of the absolute force.

$\therefore\ log\ L\,M = -\ 1{\cdot}03342\ \therefore\ log\ M = -\ 1.93305.$

$\eta' - \eta = -\ 39'$ when R = 2½ feet, and Q = 0·05734.

$\eta' - \eta = -\ 24'$ ..... 3 feet, ...0·03438.

The resulting values of B are

$$\left.\begin{matrix}0.0386\\0.0392\end{matrix}\right\}\ \text{for } I_{11}\ \text{with R} = \left\{\begin{matrix}3\ \text{feet.}\\2\ \text{feet.}\end{matrix}\right.$$

$$\left.\begin{matrix}0.0422\\0.0436\end{matrix}\right\}\ \text{for } A_{51}\ \text{with R} = \left\{\begin{matrix}3\ \text{feet.}\\2\tfrac{1}{2}\ \text{feet.}\end{matrix}\right.$$

$\therefore 0.0408$ = mean value of B.

Assuming D = 18°30′

$tan\ \varepsilon = 1.0408\ cot\ 18°30' = 3.1110 = tan\ 72°11.$

$tan\ \varepsilon + cot\ D = 2.040\ cot\ 18°30' = 6.1200.$

If the other values of B are used instead of the mean, the difference will not be of any consequence unless D is more accurately known than it is. But these differences result from an inaccurate determination of M. This quantity therefore is determined with sufficient accuracy.

For the observations for the 6th June, assuming.

$log\ 2\ X = 1{\cdot}2062$

$log\ M = -\ 1{\cdot}8700$

$\eta - \eta' = 37'$ when R = 3 feet and Q = 0·01386.

D = 18°50′

$$\therefore B = 0{\cdot}059$$

$$\therefore \tan \varepsilon = 3{\cdot}086 = \tan 72°5$$

$$\text{and } \tan \varepsilon + \cot D = 2{\cdot}059 \cot 18°50 = 6{\cdot}138$$

From the beginning of the year to the 22d May, there is no determination.

Let α be the *number of minutes* of deflection from the Horizontal line; then the variation of the vertical force will be estimated from 22d may to the end of July by the formula

$$\frac{\delta Y}{Y} = 6{\cdot}120 + \delta\eta - \frac{\delta m}{m} = {\cdot}0017803\ \alpha - \frac{\delta m}{m}$$

During August and September there are no Observations for the co-efficient.

From Oct. 4^{d}. to Dec. 29^{d}. the formula is

$$\frac{\delta Y}{Y} = {\cdot}0017835\ a - \frac{\delta m}{m}$$

Change of Magnetism in the needle.

In order to ascertain $\frac{\delta m}{m}$; the Magnet was vibrated in the Magnetometer box. The vibrations were made by a Magnet attracting without, and therefore there was no disturbance of the needle within by touching it or otherwise running any risk of throwing it out of adjustment or altering its Magnetism. Since then, by Dr. Lloyd's formula (Report of Dublin Magnetical Observatory p. 39.) T being the time of one vertical vibration

$$T = \pi \sqrt{\frac{K}{A\, m\, Y}}$$

$$\therefore -\frac{\delta m}{m} = 2\frac{\delta T}{T} + \frac{\delta Y}{Y}$$

but $Y = X \tan D$

$$\therefore \frac{\delta Y}{Y} = \frac{\delta X}{X} + 2\frac{\delta D}{\sin 2D}$$

$$\therefore -\frac{\delta m}{m} = 2\frac{\delta T}{T} + \frac{\delta X}{X} + 2\frac{\delta D}{\sin 2D}$$

$\frac{\delta D}{\sin 2D}$ must be ascertained from reducing the observations on the inclination, $\frac{\delta X}{X}$ from the corrected values of the absolute determinations of the Horizontal intensity and $\frac{\delta T}{T}$ will be obtained from the following observations; and thus ultimately $\frac{\delta m}{m}$ will be obtained.

The following observations of T were made by observing the time at which every 10th vibration ended. The observations were very consistent; and the results, which alone are given, are correct to the place of decimals entered.

DATE.	Middle time of observation.	T.	Number of vibrations.	DATE.	Middle time of observation.	T.	Number of vibrations.	DATE.	Middle time of observation.	T.	Number of vibrations.

* Disturbances destroyed the observations on each of these days.

† The inaccuracy of these days was owing to the injured state of the knife edge, in which the friction was now gradually increasing and all the observations loosing their accuracy.

Each of the observations took about half an hour to complete.

INDUCTION

was observed with a small portable instrument. It stands on a tripod base with a fixed circular plate 5 inches in diameter, graduated so as to be read off by verniers to 20″, and carrying an upper revolving plate with two projecting arms. One arm supports a telescope, the other a socket for purpose of supporting a soft iron cylinder. A rectangular box is screwed on the the upper plate to contain the Magnet, which is suspended by a single thread in a glass tube from an apparatus similar to that used in the Declination Magnetometers. The observations are made by viewing through the telescope a scale fixed near the eye piece of the telescope, the divisions being reflected by a mirror fixed to the Magnet.

The scale is divided into 30 parts, and these are subdivided into tenths. The tenths are again decimally divided by the eye; but it certainly cannot be read off with accuracy within .02 of the scale.

The solid cylindrical Magnet suspended is marked A 55; its length is 3.64; inches and diameter 0.30 inches.

The angular value of the scale was determined by turning the telescope in azimuth, after levelling the instrument and taking out the torsion of the suspension thread so that the Magnet and mirror remained in the meridian whilst the telescope moved round. Consequently different points of the scale were reflected at different angles of the telescope. The telescope was turned so that successive divisions of the scale were made to coincide with the telescope wire; and at each reading of the scale, a vernier was read off. The intervals of the scale are then measured by the difference of readings of the verniers.

Vernier.		Scale.		Value of one division.
Reading.	Difference.	Reading.	Difference.	
5° 0′ 0	0°53′20″	1·00	4·00	14′57
4·01·40	0·57·40·	5·00	4·00	14·42

358.31·40	6·42·14·	28·00	28·00	14·37
5·14·20				
Mean value of one division				14·37

July 30^{d}. 22^{h}. 12^{m}. The Magnet was suspended and lowered to within about $\frac{2}{10}$ of the upper surface of the copper box, in order that the centre of the Magnet and the

upper surface of the iron bar socket might be in the same Horizontal plane.

July 30^{d}. 22^{h}. 30^{m}. Torsion force was ascertained as usual:

Torsion Circle.		Scale.		
Readings.	Mean.	Readings.	Mean.	
33°		14·13		
	90°		0·19	
123		14·32		Reading of scale = 14·14
	180		0·37	
303		13·95		and of circle = 1°50′50″
	90		0·20	
33		14.15		

Mean..... 90° 0·19′ + 14′37 = 2′73

Hence $\frac{H}{F} = \frac{2'73}{5397} = 0{\cdot}00051$

$\therefore 1 + \frac{H}{F} = 1{\cdot}00051$

On the 20th August the co-efficient was again determined and $1 + \frac{H}{F} = 1{\cdot}00056$

Therefore the correction on account of torsion for the whole extent of scale, is but 0·01, which is too small to be considered.

The next object was to form a table which would give the declination corresponding to any reading of the scale. Readings of the large declinometer were therefore taken contemporaneously with the induction instrument on the 31st July from 7^{h}. 05^{m}. to 7^{h}. 20^{m}..

26·71	26·705	26·68	26·690						
26·70		26·70							

Taking the mean of all these observations it appears that the corresponding readings of the declination Magnetometer and the induction when used as a declination Magnetometer, are 26.703 and 14 007, but the absolute declination when the large declinometer reads 26.703, is 0°10′.676; therefore when the induction reads 14.007, the absolute declination is 0°10′.676. Upon this basis and with the ascertained value of the scale reading, table XII was constructed.

The instrument is so adjusted that increasing readings on the scale denote motion of the north end of the Magnet towards the east.

In order to ascertain whether the induction would shew the same movement as the declinometers, we made several comparisons, out of which I select those on the 2nd September 1845, as shewing most satisfactorily that although the induction is not so perfect an instrument as either of the other three instruments, yet its inaccuracy is of little importance, which will be more clearly seen in the curves of Plates III. and IV. than in the following table.

A soft iron solid cylinder 9 inches long was made at the Mint, of the softest kind which Captain Turner, Mint Engineer, could procure. It was clamped into a copper collet, and the Magnet and bar were so adjusted that the upper end of the bar was in the same horizontal plane as the centre of the Magnet. The centres of the bar and the Magnet were 0.043 foot distant from one another. This bar was marked No. I.

One end has in it a small hole which is useful as a distinction between the two ends.

An attempt was made to determine the effects of the permanent Magnetism of the bar by unclamping the collet and reversing the bar. Then half the difference between the observations is the effect.

Time.	Mean of Readings of Induc. Magnet.		
	Induction bar.		
	being removed.	with hole end.	
		below.	above.

30½	14·14		
33	....	18·43	
Mean.	....	19·00	17·92

If these means are assumed to be the correct readings, then .54 will be the correction for the permanent Magnetism of the bar. But the observations are too inconsistent to consider this as better than a rough approximation. In the registered observations the hole end was below, and therefore this correction may be subtracted from them in order to obtain the true result.

As the soft iron is very liable to rust, I considered that it would be expedient to compare the effects of a rusty and bright bar. On the last day of September the induction bar remaining rusty, another bar, which is marked No. II. and is exactly similar, and

had been placed near the declinometer No. II., was carefully cleaned, and the result shewed that the rust has no effect within the errors of observation and of the instruments.

The inconsistency of the differences between the two instruments is evidently not owing to the rust. For there is a similar inconsistency throughout the observations of the six days. It is most probably caused by the cracks which gradually opened in the wooden pillars on which the instruments were supported.

The readings of the induction instrument are made as with a Declinometer, and the mean of three extremes taken by doubling the middle reading; this mean is reduced to arc, and from this arc reading the arc reading of the Small Declinometer No. 1. is subtracted, the difference is the quantity published as the amount of induction.

1846 Jan. 9^{d}. 10^{h}. A cobweb was detected.

20^{h}. and taken out.

March 1^{d}. Since the changes in the vertical force Magnetometer had proved the general character of the diurnal changes of Y; and since these changes had not been exhibited by the curves hitherto protracted from the induction observations, it seemed possible that they might be made sensible by a longer induction bar; but it did not seem worth while to persevere with the existing apparatus. Accordingly the bar was this day removed.

Capt. H. Turner, the Mint Engineer, caused a cylindrical bar 2 feet + ·01 inch long to be made of the softest iron there available. The diamater is .0603 foot, and at one end is a small hole .02 in diameter which hole was made use of to distinguish its end as the marked end.

In order to ascertain the effect of the large bar on the small instruments the following readings were taken:

	Small Horizontal Force Mag.	Small Declination Mag.	Small Declinometer.
The induction bar was inserted in its socket, and	35·09	95·40	26·96
In taking the bar out, the induction Magnetometer was shaken; and the bar being removed through the sun from the Observatory into the shade, readings were	35·01	95·41	12·08
The bar being replaced	34·98	95·43	23·37
The bar was again removed, and also exposed to the sun in being carried to shade at a distance from the Observatory; and	34·90	95·45	12·04
The bar being replaced	34·85	95·47	23·40
The bar was again removed, but in removal carefully protected from the sun; and	34·81	95·47	12·00
The bar being replaced.	34·79	95·50	23·35

Hence it was concluded that the effect of this long bar upon the small instruments is insensible.

Early in the month of April this bar was placed in a furnace, in which, after being well heated, it was allowed gradually to cool as the furnace died out. It was kept perpendicular to the Magnetic Meridian until May 7^{d}. when the marked end being found to be the south end, the bar was put up vertical with this south end in the Horizontal plane of the Magnet of the induction Magnetometer, and with its unmarked end below.

May 29^{d}. The bar was again removed and kept at right angles to the Magnetic Meridian until June 16^{d}. when it was used in deflecting C_{IV} in order to ascertain its Magnetism both in a vertical and in a Horizontal position.

June 22d. 23h. 10m. The Magnet was removed from the induction Magnetometer and replaced by the brass weight.

22d. 23h. 20m. The torsion being destroyed, the Magnet was replaced.

23d. 00h. 35m. The reading was + 14.10. The induction bar was placed vertically with its marked end upwards for about a quarter of an hour; after which it was placed in its socket when the reading was nearly—8; and there the difference of deflection in the two positions was nearly 22.00 scale reading. Therefore the deflection caused by the Magnetism of the bar is about 11.00.

The bar was then used in Horizontal deflections.

Subsequently the bar was sent to the Mint, in order that the mechanical contrivances for its suspension might be improved, and also that it might be again turned. On its return—

July 10d. its Magnetism was again tried by Horizontal deflections. The north end was marked with a cross.

July 13d. The Horizontal deflections were again used to determine the Magnetism of the bar, which was then placed for observation.

July 18d. 1h. Bar used for Horizontal deflections.

21d. From this time the readings of the large Declinometer were substracted from the observed angle to give the deflection caused by the induction bar.

} Bar used for Horizontal deflections and replaced at the end of each observation in its socket with the north end upper most.

16. 03. 32. The bar used to deflect, and then touched as before; but the north poles of both converting Magnets were applied.

03^{h}. 50^{m}. The bar used to deflect, and then touched as before, but only three times.

04. 00 The bar used to deflect; and then left with its centre 3 feet distant from the centre of the deflected Magnet, and in an Horizontal plane, and perpendicular to the Magnetic meridian, until

13^{d}. 19^{h}... The bar was used to deflect after which it was placed in the socket. An alteration however was now made in the relative position of the bar and Magnet. For the arm, on which the socket was screwed, had been taken from the instrument and fixed to the stone pillar about 5 inches from the centre of the Magnetometer. The instrument also was then in such a position that the reading telescope, the suspension pin of the Magnets and the centre of the upper end of the induction bar were in the same Horizontal line. The final arrangements were

Oct. 19^{d}. 19^{h}. 30^{m}. the north end of the bar upper most, in the same plane with the Magnet;
the distance from the centre of the bar's north end to the centre of the Magnet = 0.355 foot;
the line joining these centres is perpendicular to the Magnetic Meridian.

The observations with Horizontal deflections, referred to above, are not sufficiently complete and decisive to publish; but they are deposited in the archives of the Royal Society. They seem however to shew, that,

1. The (so called) permanent Magnetism is continually changing and generally diminishing.
2. A part of the induced Magnetism becomes permanent.
3. Induction is not instantaneous.

THE INCLINATION

Was observed with a dipping needle made by Nairne and Blunt, and which was lent to us by Capt. Montriou, I. N. Its diameter is 9 inches and the vertical circle is divided to 15′. The dip circle does not stand upon a plane which requires levelling, but it is suspended above, and the weight of the apparatus brings the circle into a vertical plane. The extremities of the axis of the needles are cones which enter into rounded sockets; so that the bearing points may be simply two points, by which the friction is reduced to a quantity much less than the best worked axle on an agate plane. The sockets can be approximated by a slow motion; for they are hollowed out at the extremities of screws which work Horizontally in vertical pieces of brass fixed to the brass work of the circle. If the further parts of the sockets be more distant from one another than the length of the axis, then the conical ends will rest on the sides of the socket and the friction is considerable, but by approaching the sockets, the distance of their further points may be made equal to the length of the axis, and the axis is supported simply at its points and the friction will be almost insensible.

The observation is taken with north pole at the marked end, and with the face of the needle on the same side as the face of the dip circle, and with the face of the dip circle towards the east..... } in column a

The same, but with the face of the dip circle towards the west..... in column a′

With north pole at the marked end, and with the face of the needle on the contrary side to the face of the dip circle, and with the face of the dip circle towards the east..... } in column a″

The same, but with the face of the dip circle towards the west..... in column a‴

And the other columns denote similar relative positions of the needle when the north pole is at the unmarked end.

ABSOLUTE DETERMINATIONS OF HORIZONTAL FORCE

were all determined according to the method of Gauss. The Magnets used are

C 4, * *a hollow cylinder, length* 0.3208, *outer diameter* 0.058, *inner diameter* 0.049.
C 25, *a hollow cylinder, length* 0.2627, *outer diameter* 0.058, *inner diameter* 0.019.
L. M. 3, *a bar magnet, length* 1.2500, *breadth* 0.0715, *thickness* 0 208, *weight* 6203.
A 51 *a solid cylinder, length* 0.2521, *diameter* 0.024.

The units made use of are the foot and the grain.

C 4 and C 25 were observed with the small declinometer No. II. If C 25 was suspended, then C 4 was used as a deflector; after which C 25 was taken out and C 4 was vibrated. The declinometer was placed at the place marked *d* in the ground plan of

the large Observatory. South of it at the point *t* was a theodolite, which was levelled and adjusted to read off a scale which is cut on glass at the north end of the hollow cylinder magnet, and is viewed through a lens fixed in the south end of the cylinder. It is needless to explain the construction of the instrument, as it is the same as that of the Portable Declinometer described page 15 of Riddell's Magnetical Instructions.

L. M. 3 was used to deflect the Large Declinometer, and was vibrated in a building erected for the purpose. It was suspended in a box by a compound thread several feet long. But the results of the vibrations were highly unsatisfactory on account of spiders which made their way into the tube and entangled the thread.

A. 51 deflected the Magnet in the small Declination Magnetometer No. I, and was vibrated in the apparatus of the Small Declination Magnetometer No. III.

The vibrations are observed in the following manner: The time of an extreme vibration is noted, and ten vibrations are observed and the time noted. This time is added to itself, which will give the end of the twentieth vibration nearly, and the time of the extreme vibration nearest to this computed time is observed and noted. Thus the time of fifty vibrations is noted. The observed time of the fiftieth vibration is added to itself, which will give the end of the hundredth vibration nearly; and the time of the extreme vibration nearest to this computed, is observed and noted, as the true time of the hundredth vibration; in this manner the time of two hundred vibrations is observed, which divided by the number of vibrations, gives the time of one vibration. They are entered in a lithographed form as below.

Observation of Intensity. Bombay, 22nd December, 1845.

	Time corrected for rate of Chronometer..... S 3·494					$\therefore \frac{H}{F} = 0{\cdot}0015$		

The moment of inertia has been determined in the usual manner by suspending known weights at different distances, the Magnet whose moment of inertia is required being suspended in the same manner as when vibrated. If the times of vibration be unchecked by any causes, M being the magnetism of the Magnet, L its semi-length, X the earth's horizontal force, K the moment of inertia required, T the time of one vibration when no weight is suspended, T′ the time when weights p and p' are suspended on each side of the point of suspension at distances equal to r; then the equations are

$$L\,M\,X\,T^2 = \pi^2\,K$$

$$L\,M\,X\,(T')^2 = \pi^2\,(K + \overline{p + p'}\,r^2)$$

$$\therefore K = r^2\left(p + p'\right)\frac{(T)^2}{(T)^2 - (T')^2} = \frac{r^2(p + p')}{\left(\frac{T'}{T}\right)^2 - 1}$$

But the vibrations are affected by the angle of vibration, by the torsion force diminishing the angle of vibration, by temperature, and by the change of the horizontal force so that t and t' being the observed times of vibration

$$T^2 = (1 + h)\left(1 + \frac{sin^2 a}{16}\right)t^2$$

$$(T')^2 = \left(1 + \frac{d\,X}{X}\right)\left(1 + h\right)\left(1 + \frac{sin^2\,a}{61}\right)\left(1 + q\,d^\circ\right)\left(t'\right)^2$$

when h' and h, are the corrections for torsion, q is the co-efficient of temperature, and d° is the difference of temperature of the Magnet at the two observations.

$$\therefore \left(\frac{T'}{T}\right)^2 = \frac{1 + h'}{1 + h}\;\frac{1 + \frac{sin^2\,a'}{16}}{1 + \frac{sin^2\,a}{16}}\left(1 + \frac{d\,x}{X}\right)\left(1 + q\,d^\circ\right)\left(\frac{t'}{t}\right)^2$$

The moment of inertia of C 4 was determined by the following observations:

And in like manner to determine *the moment of inertia of A.* 51, it was vibrated with and without weights in the small Declinometer No. III. Previous to this the old threads were taken out and new threads 8 in number put in, so that the compound thread might be sufficiently strong to support the Magnet with large weights attached. On vibrating the Magnet with large weights attached, it was found that the time of one vibration increased with the time elapsed between suspending and vibrating it.

6 December.	
Hour of day.	Time of one Vib.
H. M.	S.
0·47	8·58
1·00	8·63
1·17	8·71
1·22	8·98
1·33	9·08

As this seemed to be caused by the gradual lengthening of the thread by the two large weights, the Magnet was left with them attached to it until the following day, when no such change was observed. The following observations were then made :

Date 1845.	Göttingen Mean Time	t	$1+h$	t'	$1+h'$	$1+\frac{dX}{X}$	$\frac{Sin^2 a}{16}$	r	$2p$	K

21st April. *The scale value of the Collimator Magnet C.* 4 was determined by fixing it near the altitude and azimuth circle, and reading off upon the vertical circle as the wire of the telescope was brought to the divisions of the scale.

Reading of		Difference of		Value of one division.
Scale.	Micrometer.	Scale.	Micros-copes.	
0	86°27′11″	3	70′25″	23′28″3
3	87·37·36	3	70·43	23·34·3
6	88·48·19	3	71·03	23·41·1
9	89·59·21			
9	89·59·19	3	71·30	23·50·0
6	88·47·49	3	70·36	23·32.0
3	87·37·13	3	70·36	23·32·0
0	81·25·37			

Reading of		Difference of		Value of one division.
Scale.	Micrometer.	Scale.	Micros-copes.	
7	86°26′04″			
10	87·37·02	3	70°58″	23′39″3
13	88·47·29	3	70·27	23·29·0
16	89·57·17	3	70·22	23·27·3
16	89·57·45	3	70·29	23·29·6
13	88·47·16	3	70·51	23·37·0
10	87·36·25	3	71·10	23·43·3
7	86·25·15			

Hence each 100th of the scale is about 14″; and therefore since the scale cannot be read off accurately within 0·02, each of these observations may be considered as equally and sufficiently correct. But the divisions between 6 and 10 probably are cut by the maker rather larger than the rest, yet the difference is too small to be regarded; the mean of the whole therefore may be considered to be the true value. Therefore each division of the scale is

$$1415'' = 23'533 = 23'35.''$$

26th April. *The scale value of the Collimator Magnet C* 25 was determined in like manner.

10	90·54·09	2	56·02	28·01
8	81·49·51	2	55·42	27·51

Hence the value of each division of the scale is

$$1679''\cdot1 = 27'\cdot934 = 27'50''\cdot1$$

or we may take 28′ which will be quite accurate for the whole length of the scale.

The Magnet at the position *d*, is unaffected by, and causes no disturbance on, the other magnets in the large Observatory.

DIURNAL METEOROLOGIC CHANGES.

The Barometer

Is a standard by Newman No. 58. The tube externally is 0·78 inches in diameter. The cistern exposes the surface of the mercury contained in it entirely to view through glass. Through this may be seen a cone whose broad end is fixed to the rod which bears the scale at the upper end of the mercury in the tube. The scale can be elevated or depressed by means of an endless screw; and before observing the vertex of the cone is made to meet the vertex of its image reflected in the mercury of the cistern; the scale will then measure the column of mercury which balances the air. The under surfaces of a projection from the vernier, (which under surfaces are a circle in the plane of the zero of the vernier) are then made tangential to the upper surfaces of the mercury in the tube. And the height of the column is read off to two thousandths of an inch by the vernier.

The cistern of the barometer is about 3·3 inches in diameter.

A Thermometer divided to degrees is fixed in the instrument with its bulb in the mercury.

When the Barometer reads 30 inches, the height of that part of the tube which is supposed to be a vacuum is 3.5 inches.

The height of the surface of the cistern above the floor of the Observatory is 4 feet 6 inches, and therefore its height above the level of the floor of the tide house is 52 feet. It is fixed dy wooden brackets into the east wall of the magnetic Observatory.

Every observation is entered into the day book, together with the reading of the Thermometer; the former is then corrected for the latter by the table published by the Royal Society. The corrected reading is then entered into an abstract, and is published under the same form.

Jan. 22^{d}. 5^{h}. 30·078, att. therm. 78°9. An air bubble had been observed towards the bottom of the tube, and therefore a suspicion was raised that there might be air above the mercury. The Barometer was therefore taken down and inverted. No air was seen to rise. The Barometer was then replaced.

5^{h}. 30^{m}. 30.090 att. therm. 80°8

·003 = reduction to 78°9

·008 = reduction to 5h. at this time.

∴ 30·079 = deduced height at 5h.

but the difference of .001 is probably an error of observation, and therefore it was concluded that there was no air in the tube.

After reversal the bubble remained in the same position. It was subsequently watched during the year and was observed to be moving upwards very slowly.

June 5d. Another barometer by Newman, marked 48 and of exactly the same dimensions and description as 58, was put up in the same place as 58.

The temperature of the air

was observed with a thermometer by Newman, with a bulb about 0·6 inch diameter and a brass scale divided to half degrees, each 10 degrees being 1·16 inch long. It is enclosed in a wooden case with glass front, and holes in the wooden sides near the bulb to immit the air.

Until the 15th April 1845, it was on the frame of the central window on the north; but as it was here exposed to radiation from the ground and also was affected by the wall, I removed it within to the meteorological stand.

In this position it is affected by radiation from the chunam floor, the walls, and ceilings. The ceiling is white, the walls of a light gray. When the windows are all open, it is free to the influence of the winds; and those to the east and west were seldom shut, except when the rain made it necessary to close the latter. The window to the east was never closed except the venetian, and that immediately to the north was also generally open. At night it was necessary to close most of the other doors on account of the lights to the magnetic instruments; and this together with the temperature from the light no doubt makes the recorded temperature of the night in excess of the truth. On the contrary, by day the temperature is probably unduly cooled; for the chunam, absorbing little or no heat, is always at a temperature less than the surrounding air; consequently the air over it is unduly cooled. The range is therefore no doubt less than the truth.

On account of these objections to its position on the meteorologic stand, four posts were erected 18 feet to the south of the S. W. angle of the large Observatory. They enclosed a square, each of the sides being 6 feet. Their height was 6 feet. They supported a bamboo roof thatched with date leaves. In the north-east corner within this hut was erected a post about 3 feet high, on which was nailed a horizontal board; the board was soaped; on it was fastened a pad of cotton, and over the cotton was a sheet of tin. Above the board was suspended a thermometer of Dr. Lloyd's construction, but with the iron-well taken off, so that the bulb was quite naked. The distance of the bulb to the surface of the tin was so short that no ray of heat, coming from the surface of the

ground at a distance of eight or ten feet, could reach it; which arrangement was intended to cut off all sensible radiation from the ground. The date roof being a bad conductor was intended to cut off all radiation from the atmosphere. Thus it was hoped the bulb would be affected by no heat except that which entered the hut laterally.

Four of Lloyd's thermometers were compared with the standard.

Since No. 2 agrees better than the others with the standard, it was hung in the hut. In order to determine the amount of heat radiated from the ground which was cut off the board, No. 1 also was hung up, on 16th Jan., at the same height in the hut as No. 2. but unprotected by the board. Jan. 18^{d}, No. 3 was substituted for No. 1.; and the comparison was continued until Feb. 20^{d}, when No. 2 was broken. The observations however had been continued quite long enough to prove that this precaution is quite essential in order to obtain the true temperature of the air, as will be seen by inspecting the table below.

No. 3 – No. 2.

In all these observations there are only five instances in which No. 2. > No. 3. They have not been corrected for differences of temperature; because the comparisons of No. 2 and No. 3 seemed to prove that the variations in the bore of the tube are so variable that no certain conclusion could be made. However No. 3 always read less than No 2; and therefore all the values of the above table are too small; and this accounts for the three minus readings. The general conclusion from the table is, that between 4h. and 19h. Bombay meantime something less than 1° was the correction for radiation; and that during the day the amount was very variable, seldom less than 1° and sometimes exceeding 5.° This large difference is no doubt smaller than that which must be allowed in most parts of the year; for that in which the comparison was made, is comparatively a cool month. And it is also smaller than must be allowed in some spots, for the ground about was partially covered with low shrubs.

One other precaution had been overlooked. No. 2 was carefully protected from the sun's rays by mats which were so adjusted from time to time by the observer that they did not obstruct the full influence of the wind on the bulb; yet it was not protected from radiation from the south wall of the Observatory. In order to correct this, a mat stuffed with cotton was hung up between the Thermometer and the wall after Feb. 2d. 19h. G. M. T.

From this time to March 19d. the standard Thermometer remained in the meteorologic stand, and the air Thermometer in the hut; the following tables give the result of the comparison.

Reading of Standard—Reading of Air Thermometer.

These differences result chiefly from the Observatory being shut and opened, partly to prevent vibrations in the instruments, and partly for the necessary comfort of the observers. The latter appears to be the principal cause. For at night the standard was always too high, and by day too low; which is caused by more doors being closed at night than by day. The excess early in the morning is probably owing to the sun heating the eastern wall. The changes of wind have also affected these results.

Since the standard had been hung previously to the 15th April 1845 to a window frame on the north wall; it was replaced exactly in the same position on the 19th March 1846, and the following are the results:

TEMPERATURE OF THE STRATUM OF AIR IN CONTACT WITH THE GROUND

was observed with a *thermometer lying horizontal on the ground*, by Newman, with a wooden scale divided to two degrees, with a bulb 0.45 inches in diameter, and with a naked bulb. The length of 10 degrees is 0 27.

From the 16th April to the 4th May 1845, it was placed in a garden border, surrounded by an Euphorbia hedge about a foot high, and containing a few plants of Poinciana Pulcherrima. It was during this time exposed to the radiation of the Sun, and also to that from the south wall of the Observatory.

After the 4th May it was placed under a narrow box, the sides of which were removable, the sides and every part of the box being painted black within. The height of the box was about six inches. The side on the sunny side of the box was always put up, but so loosely that the air would easily pass below it, whilst that on the other side was removed.

It is presumed that the blackened sides would absorb all the rays from the ground and pass most of them through the box into the air, and that the wooden outside would not conduct much heat from the sun without to the interior of the box, if any.

Some degree of inaccuracy must however have resulted from this not being the case. And the Euphorbia hedge must have hindered the surrounding air from free access, and the stratum of air within the border could not be of exactly the same temperature as such a stratum when all such impediments had been removed.

Jan. 15^{d}. 1^{h}. Comparison made with the standard

Standard.	Ground.
114°·2	114°·6
80·0	80·0

19^{d}. 0^{h}. 91° 0; but when placed upright it fell to 81°.

Mar. 20^{d}. 15^{h}. The instrument was in the sun for a short time.

May. 26^{d}. 1^{h}. The thermometer used in the astronomical Observatory was substituted.

Nov. 11^{d}. 15^{h}. The instrument was in the sun.

TEMPERATURE OF THE GROUND

was observed with a Lloyd's Thermometer by Newman. Its bulb is about 0·67 inches long and 0·40 inches horizontal diameter. Its scale is of brass and divided to half degrees. Each 10 degrees is 1·45 inches long. The bulb is plunged in an iron well.

It was placed in the same situation as the thermometer on the ground, the bulb being six inches below the surface.

Moisture

was observed with a wet bulb thermometer. Two thermometers are fixed on the same stand, their bulbs being naked. The diameter of each bulb is 0.5 inch. The scale is of brass, divided to degrees, 10 degrees being 0·4 inch in length. The interval between the centres of the bulbs is 1.2 inch. One bulb is naked, the other is covered with muslin, which is always kept moist by the capillary action of threads, which dip into the mouth of an inverted tube filled with water.

The wet bulb was placed on the same meteorologic stand with the standard thermometer. The readings of both thermometers were taken. But it was observed that the dry bulb always stood somewhat below, and sometimes as much as 2° below, the standard. I therefore compared the three thermometers together by immersing the bulbs in the same vessel and altering the temperature of the water, having previously taken off the muslin from the wet bulb. The result was as follows:

Standard.	Wet muslin off.	Dry.
82°4	82°1	82°1
78·1	78·2	78·2
83·8	84·5	83·9
86·5	87·0	86·9
95·5	97·0	96·9

But comparing this with the daily register I find

Date.	Standard	Dry	Wet muslin on.
D. H.			
April 16· 8	82°4	82°2	74°5
24· 7	82·4	81·7	77·7
May 12·13	82·4	81·9	76·5
13·13	82·4	82·0	76·2
June 9·13	82·4	82·0	80·0
14	82·4	82·5	80·2
Sep. 2·17.	82·4	79·0	74·5
Oct. 1· 6	82 4	81·9	80·0
28· 2	82·4	82·0	75.0
Nov. 17· 1	82·4	81·9	76·3
3·19	82·4	76·5	71·8
14·19	82·4	75·4	69·3
20	82·4	78·0	70·0
Dec. 8· 3	78·1	77·8	70·6
22· 2	78·1	77·1	71·2
30· 2	78·1	77·3	73·0
28·20	78·0	78·0	70·6
Nov. 23·23	86·0	85·8	75·8

Although great allowance must evidently be made for error of observation, yet these observations clearly shew that the dry bulb was depressed below its proper height, and that this depression is greater as the depression of the wet below the standard is greater. This seems accountable only on the supposition that heat is extracted from the air to form the shell of moisture round the wet bulb at a distance as far off as the dry bulb. Hence I consider the observations of the dry bulb as quite useless, and have not published them. But as the standard is under the same circumstances as the wet bulb, these two may be used in calculations for humidity, so long as the standard was on the meteorologic stand.

Feb. 28d. 11h. A wet bulb thermometer exactly the same as the above was placed on the meteorologic hut upon the tinned board, by which ground radiation had been cut off from the air thermometer. As it was equally essential that the bulb of this thermometer should not be exposed to the wind, and that it should be in the same body of air as the air thermometer when the latter was exposed to the wind, a small mirror about an inch square was put on a little stand; and this being placed upon the tin board could be moved about by the observer into such a position that it might always cut off the wind from the bulb of the wet thermometer only. In order that the observer might know the direction of the wind, a small vane also was put on the board. The reason for making use of a mirror for a screen was that it would radiate no heat on the air thermometer; and therefore the glass side was always turned towards the bulb of the air thermometer.

Both the outside and the inside thermometers were thenceforward observed until the 11th May. The following tables give the results of the comparison.

Reading of inside wet bulb—Reading of outside wet bulb.

The above discrepancies are functions of 1st the differences' of reading of the thermometers at the same temperature, which may amount to 0°5; 2d. the exposure to drafts of air within the Observatory, which would diminish the reading of the internal thermometer; and 3dly the retention of atmosphere within the room which would have a tendency to keep up the reading at any time to whatever it had been at a time preceding. The latter seems to have been the principal cause of the errors of the internal thermometer. This consideration furnishes an explanation of the great discrepancies of the 15th, 17th and 18th March. For a sea-breeze on the 14th having brought into the Observatory a large supply of moisture, this was only gradually removed by the dry land wind which was blowing at 0h. on the 15th; so that the moisture of the sea breeze was indicated for several hours within, whilst the dryness of the land breeze was indicated by the wet-bulb without. In like manner on the afternoon of the 16th, there was a sea-breeze and its moisture was registered by the inside wet-bulb, whilst the land breeze was actually blowing on the 17th. On the 18th a sea breeze had been blowing from 18h. of the 17th to 14h. of the 18th; this may be supposed to have accumulated moisture, and such was in fact indicated by the outside wet-bulb according to which the air was nearly saturated at 11h; but the atmosphere in the interior of the Observatory never came so near the point of saturation, but was kept much more nearly in the same state of moisture from 2h. to 11h. If, on any one of these three days, the doors had been kept open, the room would have been nearly in the same condition as the open air, and such large discrepancies as 3° would not have occurred. In the hot days of May, the observers most probably kept the doors well open, and consequently the two wet bulbs agree pretty well during this month.

A large discrepancy occurs April 27d. 18h. The sign here is —. This morning was very hot and a fresh sea breeze was springing up. The Observatory was then doubtless open, the breeze blew upon the unscreened bulb of the interior wet bulb, and unduly oppressed it; the exterior thermometer was screened, and therefore gave the true moisture.

April 19d. 22h. The screen was away.

Daniel's Hygrometer of the usual construction is used for the determination of the dew point, the observations being made at the meteorologic stand, until March 19d. 23h. from which time it was observed in the meteorologic hut.

Direction of the wind

is self-registered by an anenometer on Osler's principle. It is made by Newman. The vane is above the roof of the transit room, and the table and clock are at the west end of the room.

Pressure of the wind

is measured by Lynn's wind gage. The tube is of equal diameter with the orifice where the wind enters. The pressure of the wind, corresponding to the heights at which the column of water rises, is ascertained by the table given in the Report of the Royal Society's Committee for 1840, page 84.

Evaporation

is measured in the funnel top of a rain gage; the upper diameter is 12 inches, the lower diameter 4 inches, and the depth is 7 inches. A bar is placed on the upper surface and carries a needle. At 5^h. and at 17^h. the point of the needle is made to touch the surface by dropping water into the vessel, until the points of the needle and its image meet. The water is dropped from a graduated tube, so that it is known exactly how much water is dropped in every six hours, and consequently how much has been evaporated during that time.

The vessel is placed in the N. W. angle of the Observatory close by the wall. In this corner there is no wind, and the walls make it difficult for the evaporated moisture to pass away freely as in the case of natural evaporation. Besides this, the temperature of the water and surrounding air is affected by the disadvantages pointed out with regard to the other meteorologic instruments within the Observatory. These circumstances must be taken into account in making use of our registers.

Two other rain gages of a like construction also were used to determine the evaporation. They were sunk into the ground with their brims nearly at a level with the soil, in a very clear space between the Observatory bungalow and the large Observatory, where the wind had free access to their surface. They were both protected by iron wire, to prevent birds or other animals drinking from them. There was also a stuffing of cotton round about them in order to prevent as much as possible the conduction of heat from the surrounding soil. In the Register they are distinguished as Dish No. II. and Dish No. III. No. II. was protected by matting which was changed in position by the observer on duty so that the sun's beams might be cut off from the vessel, at the same time that the wind had free access. No. III was exposed to the full influence of the sun.

Rain.

Osler's Rain Gage is connected with the anenometer. It is 55 feet above the floor of the tide house. It exposes to the rain an area of 288 inches. The collected water passes through a tube into a vessel suspended in a frame by a chain which pass over a wheel and supports at the other extremity a weight, which is made variable so as to

counterbalance the variable weight of water in the vessel by being immersed in water. The self registering apparatus is the same as that described in the Greenwich Observations for 1840-41.

Newman's Rain Gage, is a funnel whose upper diameter is 12 inches, it is placed about 35 feet from the north-east angle of the Magnetic Observatory. It is about 49 feet above the floor of the tide house.

Oct. 4^{d}. 10^{h}. Newman's Gage was out of order.

Solar Radiation

was observed with Sir J. Herchell's *Actinometer*.

In the register the day of the month is the civil day, the hours before 12 belonging to the preceding day.

It was also observed with a *black bulb thermometer*. The thermometer is exactly the same as the thermomenter on the ground employed to determine the temperature of air in contact with the ground. It was fastened to a wooden bar placed in a wooden box, which the observer could always adjust so as to bring the plane of the thermometer perpendicular to the sun beam.

The observations with the black bulb were suspended when the sky was too much clouded.

From June 1^{d}. the observations were continued until the hour after sunset.

June 10^{d}. 15^{h}. The thermometer was cooled by rain.

Oct. 15^{d}. The thermometer, which at the commencement of the year had been used as a ground thermometer, having had its bulb blackened, was fixed on a wooden frame exactly the same as that of the thermometer hitherto used as a black bulb, and placed in the same way in the same box with it. The bulb was then screened by a small wooden bridge, blackened internally in order to absorb and not reflect any rays from the bulb or the parts of the apparatus about it, and other precautions were taken to prevent the bridge from being heated by the sun. This was done because it was suspected that the readings of the exposed black bulb were caused partly by the heat of the box and of its scale. If this were not the case the readings of the air and screened black bulbs would have been nearly the same. They were however very different; so that in order to obtain the effect of solar radiation it will be necessary to subtract the screened black bulb and not the air Thermometer reading from the unscreened black bulb reading.

Dew.

Preparatory to making a series of observations on this meteorologic element, which is of immense importance relative to the agriculture of India; the following experiments were made in order to determine the most eligible position for making them.

These experiments were made with wool, which was cleaned with potash, and further by vapor of sulphur. Out of a quantity thus prepared, balls, with the fibres very loose, were made, and tied with cotton thread by which they were suspended at different heights from the ground. The place chosen for the experiments is on the east of the broad walk leading from the large Observatory to the Bungalow; and the trees and shrubs which might affect the radiation were cut away, with the exception of a low edging of euphorbia which bordered the walk and might hinder westerly winds from blowing freely on the surface to a height of a few inches. No. I. was suspended close to the ground which was of red soil; No. II. at a height of eighteen inches, and No. III. of thirty above the ground; Nos. IV. and V. were hung from an iron wire between two poles about six feet high; No. V. was nearest to the other three balls, and No. IV. was nearer to the large Observatory.

The balls were weighed in a balance by Robinson, belonging to the Elphinstone Institution, a little before sunset. After sunset they were suspended and hung all night, and were weighed in the morning. In general, it was not possible to weigh all five balls within the same hour on account of the numerous other observations to be made at the same time. But when three only were observed, the weighing was completed within the half hour which is entered as the time at which the gain was determined. After the observation, the ball was in the sun during the day.

The unit of weight is the grain.

A ball of seven grains weight was found to be sufficiently delicate; and it was an object to have the balls as small as possible in order that the air might freely permeate.

The difference in weight of the supposed dry balls each day appears owing to their never being perfectly dry, the moisture in the air always affecting them. On this account the weighing was repeated in the latter part of the series more frequently than was at first thought necessary.

From the following observations it will appear that the euphorbia hedge must greatly have affected the observations; consequently the position No. IV. was considered least objectionable for carrying on a regular series; and accordingly, they were regularly made every hour during the night after the rains.

* Dew was perceptible only on the leaves of the plantain at day break.

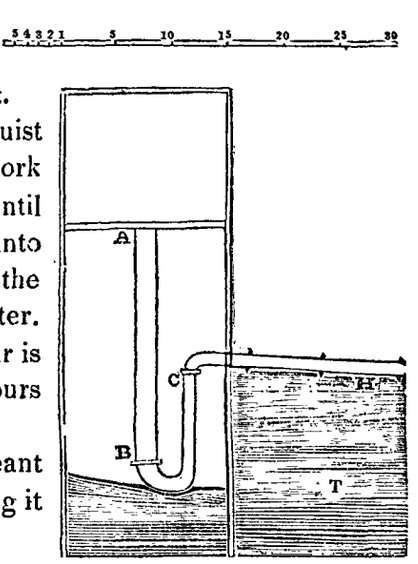
‡ New balls.

† No perceptible dew.

Tide Gage.

The tidal changes are observed by a self-registering gage which is placed in a small building in the east of the Observatory compound. The float of the gage descends into the pipe AB. in which the water rises, being conducted by the syphon B C H from below the low water mark T.

The diameter of the pipe B C is..... 9 inches.
Of the pipe C H ..... 6 inches.
The length from C to low water Mark.... 780 feet.



This construction was recommended by Dr. G. Buist and on resuming charge in April 1845, I found the work considerably advanced, but it was not completed until after the rains; therefore we were not able to bring it into operation until December 1845. Since that date the curves have been traced on the paper by the self register. And as it was found that the curve for each half hour is always nearly coincident with its tangent, the half hours only have been abstracted and published.

The gage was under the immediate charge of Serjeant Dunn, who took most praiseworthy pains in keeping it in order and watching its working.

The highest tides come up to the wall of the building. As far as the pipe extends, the shore is rocky and gradually descends, since the trap beds dip towards the sea in the deep channel which forms the entrance to the harbour, and which lies between Colabah and the Prongs on the west side, and the island of Caranjah and Angria's Colabah on the east side. This gage therefore indicates neither the tide of the open sea nor that of the harbour but something between the two.

Weather.

In recording these observations the following symbols are always used:

`	Cirrus.	` *i*	Cirri.
∩	Cummulus.	∩ *i*	Cumuli.
—	Stratus.	— *i*	Strati.
∿	Cirro-Cumulus.	F.	Prefixed signifies fleecy.
⌒	Cirro-Stratus.	D.	Prefixed signifies dense.
⌒	Cumulo Stratus.	L.	Prefixed signifies light.
∿	Nimbus.		

Arrangement of Duties.

The hourly observations were made by Ananta Ballal, Gunesh Narrayan, and Dinshaw Dorabji. On occasion of sickness their turns were taken either by Keru Luxamon, or Serjeant Dunn. The part which each took in these observations, will be seen by the initials placed to the hourly observations of the weather; for it is to be understood that all observations made at the hour, were taken by the same individual. The initial letters are as follows:

ID. Sergeant Dunn.
K. Keru Luxamon.
A. Ananta Ballal.
G. Gunesh Narrayan.
D. Dinshaw Dorabji.

The order of the observations themselves as taken at each hour is

From 20m to 7m	before the full hour	The Weather is observed.
7 to 3	.....	The Meteorological Instruments.
at 2	.....	The Vertical Force.
at	the full hour.....	The Large Declination.
2	after the full hour..	The Large Horizontal Force.
4	.....	The Small Horizontal Force.
5	.....	The Small Declination.
	and as quickly as possible	The Induction.

The remaining time is occupied in abstracting and reducing.

Myself, Serjeant Dunn, and Keru Luxamon, divided the experimental and preliminary adjustments. The adjustments and determinations of the co-efficients of the small instruments were made entirely by Serjeant Dunn and Keru Luxamon. The fixing the instruments, the cleaning and the various other mechanical operations mentioned in the Introduction were left to Serjeant Dunn. The absolute determinations of Dip and Horizontal Force were taken partly by Serjeant Dunn, and partly by Keru Luxamon. I was personally engaged in the other determinations, and, as I always examined the work of the two principal assistants and was called when any difficulty occurred, I am responsible for the accuracy of the whole. Serjeant Dunn, and Keru Luxamon, or one of them, were always present; I considered it essential to the stability of the establishment that they should be perfectly acquainted with the objects and principles of the observations in a country where sickness causes very sudden removals, and the establishment might be left (as it has been) without a superintendent. The zeal of both of them has greatly assisted me, and I cannot separate their work from my own so far as I was engaged in the observations.

The hourly observations are inspected by me frequently. In order to facilitate this, the curves of the principal instruments are pricked off at the time of observation, which enables me to see at a glance whether they are working correctly.

The Tables in use have been calculated by Serjeant Dunn and Keru. They are hung upon boards over the registry table.

MISCELLANEOUS

Observations at Surat, the Keneri Caves, Mahableshwar, Nagootna, and the road between Nagootna and Mahabaleshwar.

These observations were made, when I was on educational duty at Surat, and the others when ill health obliged me to leave Bombay for a short time. Those at Surat were taken on a terrace at the top of the Government School-house. The instruments were under the protection of a bamboo matting. At the time, I was in a very nervous state of health; my mind had been much fatigued by long school examinations; and I was a good deal interrupted by the curiosity of Mr Green's pupils, to whose curiosity I was quite willing to sacrifice the observations. Consequently great errors were made, and on returning to Bombay I doubted altogether the accuracy of my observations, I made them over however to Keru Luxamon, who made out the following results:

Longitude of the School House, Surat.

The instrument used was a small variation transit by Robinson.

Date.	Stars observed.	Equatorial intervals between the wires.			
		I and III	II and III	III and IV	III and V
Nov. 7D.	γ Ceti.....	45·0	22·0	23·0	50·0
	α Ceti.....	44·7	23·7	23·3	50·2
9	α Eridani..	....	....	22·5	47·9
10	α Ceti.....	44·0	23·0	24·0	49·0
	α Persei...	46·7	22·9	23·5	49·6
11	α Eridani..	47·4	22·8	24·8	49·5
	α Arietis ..	41·3	21·1	21·1	45·9
	γ Ceti.....	44·0	22 0	24·0	54 8
	α Ceti.....	....	...	24·0	54·0
	Polaris ..	45·6	22·8	....	50·5
	Means.....	44·7	22·5	23·4	49·9

Assuming the above means to be the true intervals, the following intervals were calculated for the undermentioned stars:

	Time of passing between the wires.			
	I and III	II and III	III and IV	III and V
	m. s.	m. s.	m. s.	m. s.
Polaris.....	28·09	14·10	14.44	31·25
α Eridani.....	1·24·4	0·42·5	0·44·2	1·34·2
α Arietis.....	0·48·4	0·24·4	0·25·4	0·54·1
γ Ceti.....	0·44·7	0·22·5	0·23·4	0·49·9
α Ceti.....	0·44·8	0 22·5	0·23·5	0·50·0
α Persei.....	1·08·6	0·34·5	0·35·9	1·16.6

With these quantities each of the observations over each wire was reduced to the third wire, and those which differ much from the other being rejected, a mean of the others only was taken. For example,

7th Nov.	Observed passage	Reduction	Reduced Observation.	
α Ceti over I	$12^h\ 02^h\ 38^s0$	44·8	$12^h\ 03^m\ 26^s8$	rejected.
..... II	02 59·0	22·5	21·5	
..... III	03 22·7	..	22·7	
..... IV	03 46·0	23·5	22·5	
..... V	04 13·0	50·0	23·0	

∴ Mean passage of α Ceti = $12^h\ 03^m\ 22^s4$

In this way the following transits were determined.

	h. m. s.
1846 Nov. 7d γ Ceti.....	11·44·33·0
α Ceti.....	12·03·22·4
9d Polaris.....	10·14·25·0
α Eridani.....	10·34·02·0
10d α Eridani.....	10·30·18·0
α Airetis.....	10·56·38·9
α Ceti.....	11·52·18·2
α Persei.....	12·11·34·2
11d Polaris.....	10·09·53·0
α Eridani.....	10·26·34·3
α Arietis.....	10·53·09·7
γ Ceti.....	11·29·53·9
α Ceti.....	11·48·40·8
α Persei.....	12·08·13·6

After these observations were completed, the instrument was turned and changed in another azimuth, and Polaris was observed with the lamp and instrument reversed; and the error of collimation deduced $207^s.4$ for the pole star, or $+5^s\ 4$ for equatorial stars.

From the observations of Polaris and γ Ceti the horizontal deviation was computed—$5^s.\ 1$.

The error of level was assumed $= 0$.

The observed time of each star's passage being corrected for the above errors, the error of the chronometer was ascertained for each star according to the usual method of the Bombay Observatory; thus,

	h. m. s.
Mean time of γ passing Meridian at Greenwich	8·37·35·6
Correction for long $4^h\ 51^m$	47·9
Mean time of γ passing meridian at Surat	8·38·23·5
R. A. of Ceti	2·34·58·6
True Mean time of γ Celi passing meridian of Surat	11·13·22.1
Time of the same by chronometer	11·30·00·0
Error of Chronometer	— 16·37·9

Column II, in the following table contains the errors of the chronometers thus calculated from the stars in column I. Some of these are evidently erroneous. Keru conjectured that I had probably taken some multiplie of $5^s.$ wrong, of which I have little doubt, and such probable errors are entered in column III. Col. IV contains the corrected errors of the chronometer; col. V, the mean for each day; col. VI, the resulting rates; col. VII, the deduced error of the chronometer on the 5th November.

Date.	I	II	III	IV	V	VI	VII
		m s			m. s		m. s
Nov 7D.	γ Ceti.....	-15·34·3	0·0	-15·34.3	-15·33·4		-14·53·9
	α Ceti.....	-15·32 6	0·0	-16·32·6		s	m s
9D.	α Eridani..	-16 04·5	0·0	-16·04·5	-16·04·5	-15·6	-14·53·4
10D.	α Arietis..	-16·10·2	+10·0	-16·20.2		s -16·7	
	α Ceti.....	-16·16·6	+05·0	-16·21·6	-16·21·2		m s -14·54·3
	α Persei ..	-16·31·8	-10·0	-16·21·8			
11D.	α Eridani..	-16·25·3	+10·0	-16·35.3		s -15·7	
	α Arietis..	-16·38·1	0·0	-16·38·1			
	γ Ceti.....	-16·37·9	0.0	-16·37·9	-16·36·4		m s -14·53·7
	α Ceti	-16·34·5	0·0	-16·34·5			
	α Persei ..	-16·66·2	-30·0	-16·36·2			

∴ The mean value of the deduced error for Nov. 5^d. is $-14^m.\ 53^s.\ 7$

But the error of the chronometer for Bombay Time on that date by the register of chronometers at the Observatory was ..... $-14^m.\ 31^s.\ 6.$

∴ The difference of the longitude of the two places is..... $22^s.\ 3.$

The School-house at Surat being East of the Bombay Observatory.

Latitude of the School-House, Surat.

The barometer was assumed 30 inches, and thermometer = 80° F. and the following colatitudes were deduced.

	Observations.	Deduced colatitudes.
α Eridani	10°53′40″	68°48′16″
α Arietis	1·33·10	68·48·24
γ Ceti	71·24·00	68·48·20
α Ceti	72·19·00	68·48·14

∴ the latitude is 21° 11′ 42″

MAGNETIC DECLINATION.

All the observations were made with a small Magnet suspended in the small Declinometer No. 2; and the readings were taken with the variation transit.

The observations at Surat were made on the top of the School-house which is situated close by the river in the midst of the town.

Those at Mahableshwar were made by myself and Keru Luxamon, under shade in the grounds of the bungalow belonging to Col. Dickinson. The rock of these mountains is trap capped with laterite. The height of the barometer is about 25.5 inches. Its longitude is about 76°40′ and latitude about 18°.

These being made in the open air are reduced to absolute observations by ascertaining the position of the Magnetic Meridian, correcting for the errors of the transit, for torsion.

Those at Kenneri being made in the principal cave when stars could not be observed, are only variations of declination. The cave is hollowed out of a volcanic tufa.

OBSERVATIONS AT ADEN.

At the request of the Bombay Military Board, I prepared an Ostler's wind-gage, a mountain barometer, by Adie, a self-registering tide-gage, and thermometers for

observations to be made at Aden. The following is the comparison between the Bombay Standard No. 58 and the mountain barometer on different days.

At the hour	Barometer. Uncorrected for Temp. No. 58.	Aden.	Corrected for Temp. No. 58.	Aden.	No. 48. — Aden.	Attached Thermometer. No. 58.	Aden.	Aden. — No. 58.	At the hour.	Barometer. Uncorrected for Temp. No. 58.	Aden.	Corrected for Temp. No. 58.	Aden.	No. 58. — Aden.	Attached Thermometer. No. 58.	Aden.	Aden. — No. 58.
0	30.082	30.114	29.936	29.968	- .032	82°5	82°4	- 0.1	12	30.072	30.128	29.970	30.004	- .034	75°2	74°6	- 0.6

The instruments were put under charge of Serjeant W. Moyes, who was furnished with forms of observation from the Observatory. By the 1st April he had set up his barometer and thermometer in a bungalow belonging to the Rev. Mr. Tombs, in an open worked verandah 12 feet wide, and which he protected with tent walls to keep off radiation.

It had been proposed to establish the meteorological instruments at Seerah, a rocky islet, ~~south~~ of the peninsula; and which therefore is protected from the ~~northerly~~ winds by the high mountains of Aden. In order then that the amount of obstruction might be estimated, I requested Serjeant Moyes to observe the altitudes and bearings of the principal heights.

Places Observed.	Observations made at Highest Pt. of Seerah. Angular height.	Azimuth.	Marshag. Angular height.	Azimuth.	Munsiry. Angular heights.	Azimuth.
Seerah			0°50′00″	172°00 W.		65°00 E.

Extreme South Pt.				50·10 W.		
Marshag	0·50·00	18·00 E.			2·00·00	45·00 E.

Nov. 2. The anenometer being not yet put up, Serjeant Moyes noted the wind by three vanes, one on the highest point of Seerah, one on the top of the Flag staff at Seerah, and one on the top of his house which had been built at Seerah.

The tide house was built according to a plan ~~which I gave in to the Military Board~~. As the shore is shelving, I wished as far as possible to obviate the effect of friction and other retardation in coming up the shore, and therefore wished the tide house to be as far out to sea as possible. Also I wished to have the indications direct and not through the medium of any piping or channels, which must cause the indications to correspond to a time prior to that which is registered; and also to diminish their amount. The chamber therefore to receive the gage was elevated on ~~four wooden pillars driven into the shore at low water~~; and the float moved in a vertical tube also driven into the shore with holes to admit the water from below. The tide house was to be visited at low water, or in a boat at high water.

Dec. 15. Serjeant Moyes, writes: "The tide gage is finished and at work; but I think it will be best to put a fresh paper on every day, as the tides do not range more than 7 feet at spring and 3 at neap tides; and I think that the curves will be too much confused, if left on for the whole month. The first day it was set up I thought that it would not answer, as there was a curve traced eight inches broad, through a strong current caused by a strong S. E. wind. These currents are rare. I have however proposed a plan, which the Engineer Officer has approved of. It is to make another pipe about 4 feet long to fit over the other, and with only one row of holes pierced in it; this is to be let down over the present pipe and close its operations when the surf is high."

A set of instruments similar to those at Aden had long been prepared for Kurrachee. No one, however, was found willing to undertake the observations there. Consequently it was proposed to send the Kurrachee anenometer to Aden to be placed on Shumsham, the highest point of Aden, 1,760 feet above the level of the sea. This having been sanctioned by Government, the anenometer arrived at Aden some time before Dec. 29d.

29d. Dec. Serjeant Moyes writes "From 3 P. M. of the 15th to 9 A. M. of the 16th the float caught against one of the rivets of the tube. I cannot attend to the gage as often as I wish, not having a boat, and I often have to swim to it at high tides.

The locality for the tide-gage was recommended by ~~Capt. Haines~~ I. N.

TABLE II.

Distance of the axis of the Bar Magnet, in large Declination Magnetometer, from the central wire of the Transit Instruments in minutes of arc, uncorrected for Torsion or error of Transit, corresponding to Readings of Transit Instrument.

* Most probably a Cobweb on the instrument.

† The Magnet was freed from it by producing a Vibration.

Note.—This month was more cloudy than the last. The number of hazy days was increased; dense fleecy clouds prevailed for some time. The horizon was always either misty or cloudy. Where these clouds were thought to affect the Thermometer, those observations are marked with the clouds that prevaild at the time on or near the sun.

Note.—This month was less hazy, but more cloudy than the last month. \i and light and dense fleecy clouds were the prevailing clouds. Observations that seemed to be affected a little by these clouds are marked with the clouds that prevailed at that time on or near the Sun; but those that were considered to be affected very much were dropped.

MAY, 1846.

Note.—Many observations were lost in this month by the increasing number of dense fleecy clouds, which sometimes changed into Nimbi obscuring the whole of the sky and frequently the Sun. Those observations that were not much affected, are marked by the names of clouds that prevailed at those times on or near the Sun.

31														

Note.—In this month the Monsoons regularly set in, and the appearance of the sky is so much altered that it is very seldom that there is any hope of having the Sun clear even for a short time. The above observations must not therefore be considered as free from the effect of clouds, but on the contrary, taken always with the face of the Sun obscured by either Nimbi or dense fleecy clouds. Observations, when it was raining, were rejected.

A very remarkable Meteor was observed by Karu Luximon, the 2nd Assistant, whilst walking on the Sea shore, about 300 yards distant from the Observatory, a short time before day break (16h. 45m. B. M. T.) on the morning of the 7th December, 1846. Having his eyes fixed on the ground he suddenly had the sensation of a flash of very vivid lightning, although at the time the moon was bright enough to dull any ordinary bright and sudden light. He looked up in the direction whence the flash seemed to come, and saw a Meteor, like a star of the 4th Magnitude, passing in a horizontal line towards the North: behind it at an interval of about 10° there was a band of light the breadth of which was about ⅔ of the moon's diameter or about 5′, and its length about 5°. The maximum brightness was in that part of the band nearest to the Meteor, and about ¼ of its whole length from the extremity: the band faded gradually away from each end towards its centre so that it had much the appearance of a comet.

The maximum brightness he estimated at ten times that of Jupiter's. The Meteor disappeared in two seconds nearly 15° from the brightest part of the band; but the band remained for the of space 10 seconds after he first saw it, without altering its position, although diminishing in brightness: the brightest part of the band was about 5° in a vertical line below the star Sirius.

The tail of a Meteor has been supposed to be a mere optical delusion, the light of the Meteor combining with its rapid motion, like the electric spark in the case of lightning, leaves a continuous impression upon the eye. This is however fully disapproved in the present case—For the Meteor was quite detached from the tail. Secondly, the band was stationary during the time of its appearance. Thirdly, he moved his eyes repeatedly to different parts of the heavens, and saw nothing of the band, until he again directed his eyes in the direction where he first saw it, and then it was just in the same position as before.

Many other persons witnessed the same phenomenon on the Island of Colaba.

BOMBAY, 1846.

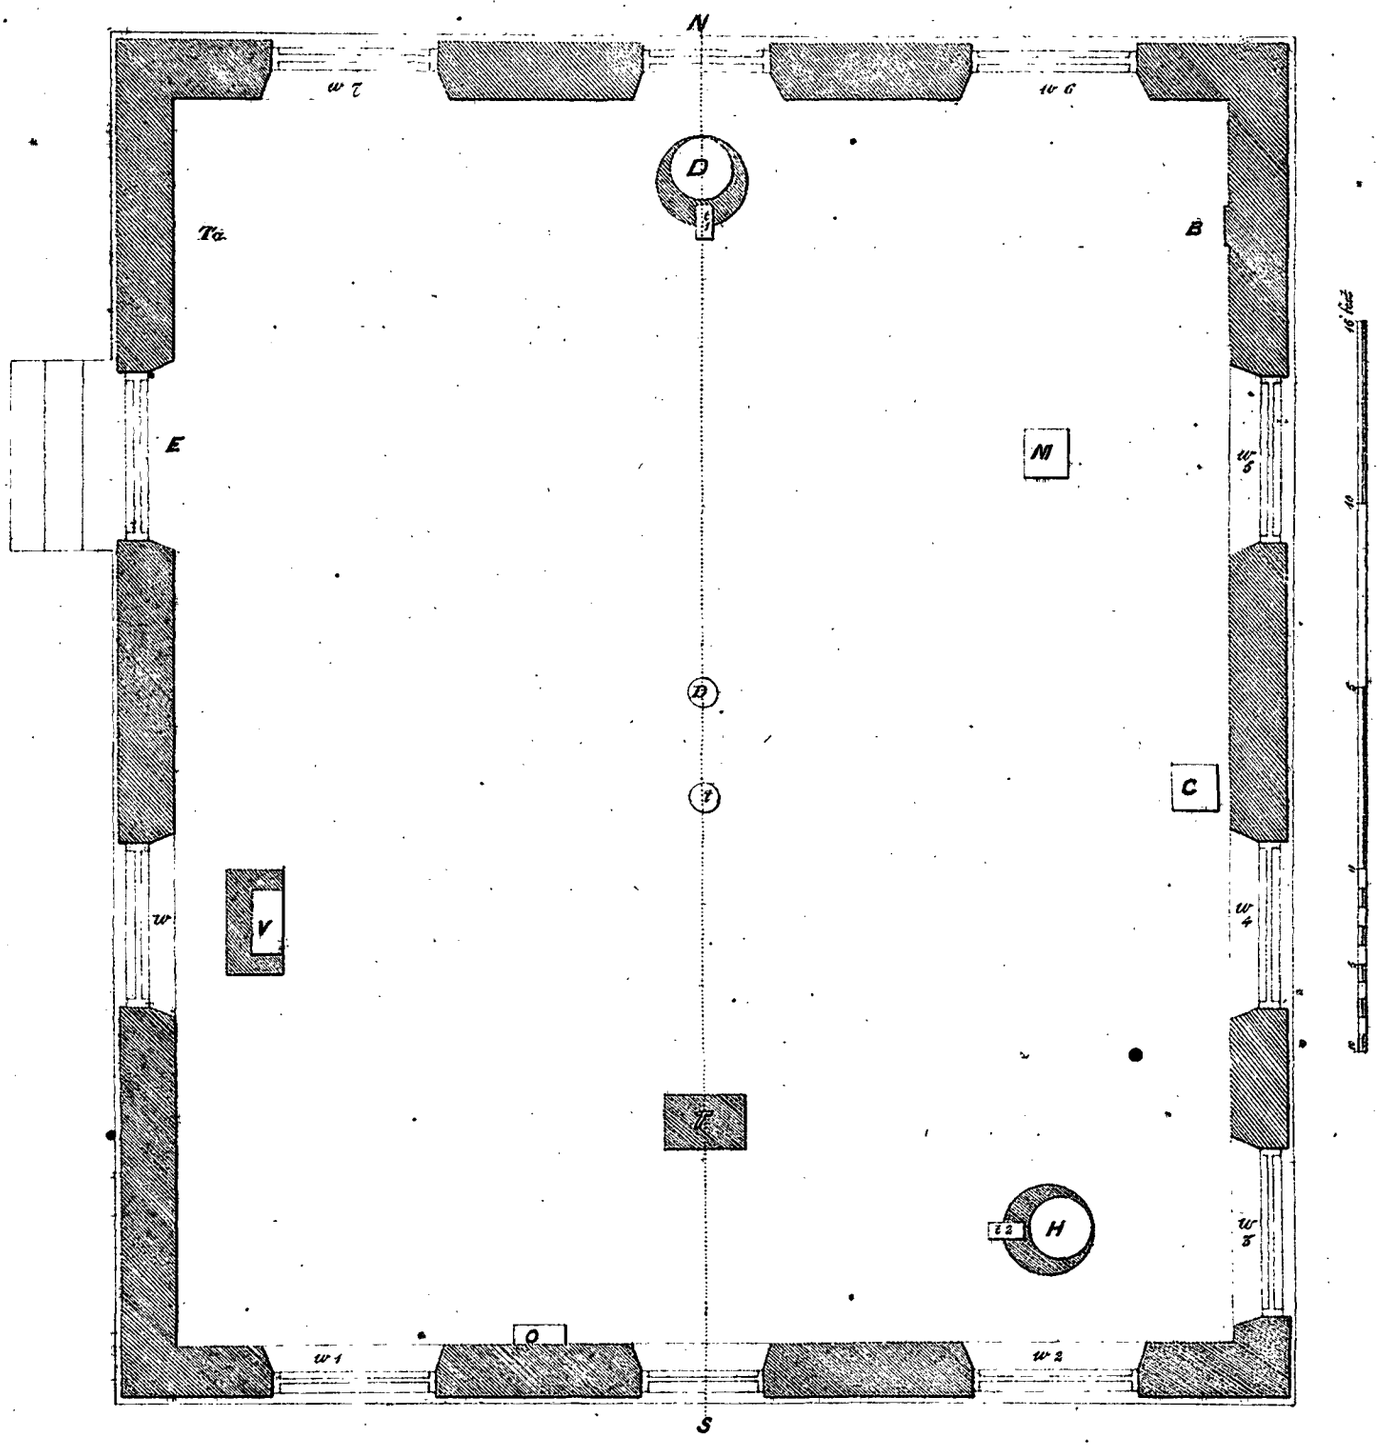
BOMBAY

MAGNETICAL OBSERVATORY

Ground Plan of the Large Observatory, Shewing the Disposition of the Instruments



D. Large Declination, V. Vertical Force, H. Horizontal Force, D. Small Declination Magnetometers. N.S. Astronomical meridian; T. Small Transit; B. Barometer; C. Chronometer; M. Meteorological Stand; t, t1, t2. Reading Telescopes. E. Door; Ta. Table for books and Calculations; w, w1, w2, w3, w4, w5, w6, w7. Windows; O. Mean Time Clock.

The unshaded circles mark the bases of the Magnetometers, and the shaded shew the circumference of the masonry pillars on which they stand.

Lith. at the Observatory, Bombay.

Scale 8 ft. to an Inch. 15 Oct.

MAGNETICAL OBSERVATORY BOMBAY
